I exhausted all puddles from two snow dumps this morning (19 April 2024, Rovaniemi) and got heaps of Ujvarosi stars. Here is one of them at the old snow dump by the bog Isoaapa (actually, not "old" anymore for they have just opened it after being closed all winter - they are still removing the snows even if much has melted already). The interesting thing is the second colored parhelion on the right pointing spike, best at about 00:10-00:25. The options are 46° stuff through 90 degree prism, rotated parhelion (from three prism face hit raypaths) and parhelion of parhelion. The outer parhelion colors are not any deeper from the inner one so I would be inclined to count out the first option. Ujvarosi has also similar feature in her standard setting observation (the second last image of four photos): <https://t.co/TSOowbjoMI>

At first the plate topside is facing camera, at 01:16 I turn it around. From 01:57 the bottomside is up

Another plate – I think from the same puddle – containing again the outer colored parhelion (19 April 2024, Rovaniemi, old snow dump). The rotated parhelion would be expected to be at around 46 degree distance only at a specific crystal rotation and tilting the plate should make it move differently to the normal parhelia spots. I am inclining on parhelion of parhelion being the right explanation.

It's gonna be another cold night, but looks like morning might be cloudy. If I get myself up, I may go and try how this works in spotlight beam. May be necessary to use blocker as spotlight tends to otherwise glare out everything.

This is the only plate where I see parhelion spot and white spot switch places, in the beginning of the video on the left side arm (19 April 2024, Rovaniemi, old snow dump). Or at least I see the white spot crossing the location where the parhelion was. From 01:15 the outer colored parhelion is once again visible on the right side arm. Does it have deeper color than in previous videos? Maybe the basic 46° spot is still an option. At first the topside is towards the camera, then bottomside.

There is a faint light bridge between the white spots of adjacent arms. Seen first on the left side, then on the right.
