A piece of home-grown plate showing parhelion with a weak parhelic circle connecting to the bright spot. It occurred in the protruding growth that makes the surface granular. All worth watching is in the beginning of the video. I should have rotated the plate while at the same time trying to keep the surface on which parhelion occurs in place. If the parhelion would have remained, it would have told that the crystals are not az-locked. The connecting parhelic circle might suggest this, or then it is formed in a related manner to the other white arcs. Anyway, Ujvarosi got similar thing nicely captured: <https://t.co/tmkivvnrEC> Best seen in the videos which are linked at the end of the post.

I tried to photograph the crystals but botched it. It is very easy to make fatal mistakes with this stuff. Anyway, I think my microscope setup of photographing always perpendicular to the plate is not the best. Should maybe try to incline the plate.
