1/27 - 2025-07-05 13:17 UTC

I was in Chiang Mai the full months of April and May 2023, observing halos. I will publish the results here. April was still much the dry season, largely devoid of high clouds, giving only 4 displays. This 573 frame stack (interval unknown) is of the first one, on 8 April.

2/27 - 2025-07-05 13:17 UTC

The second Chiang Mai display, on 10 April 2023, I deleted accidentally from the phone. The halos – pillar and tanarc – appeared while I was visiting the immigration. The pillar suggested that I was north

enough to be outside of the curse of the equator. (Photos are of my base).

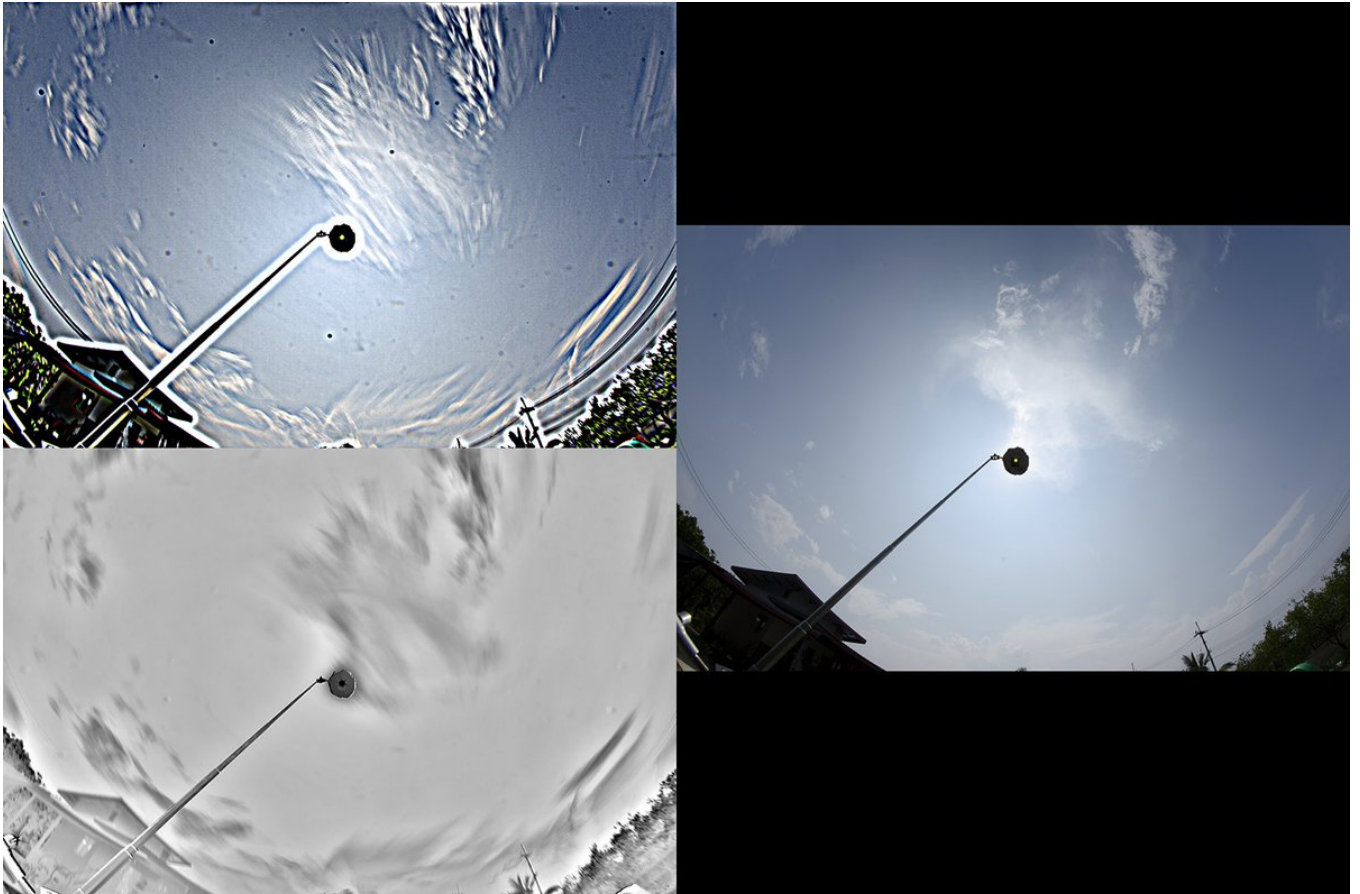

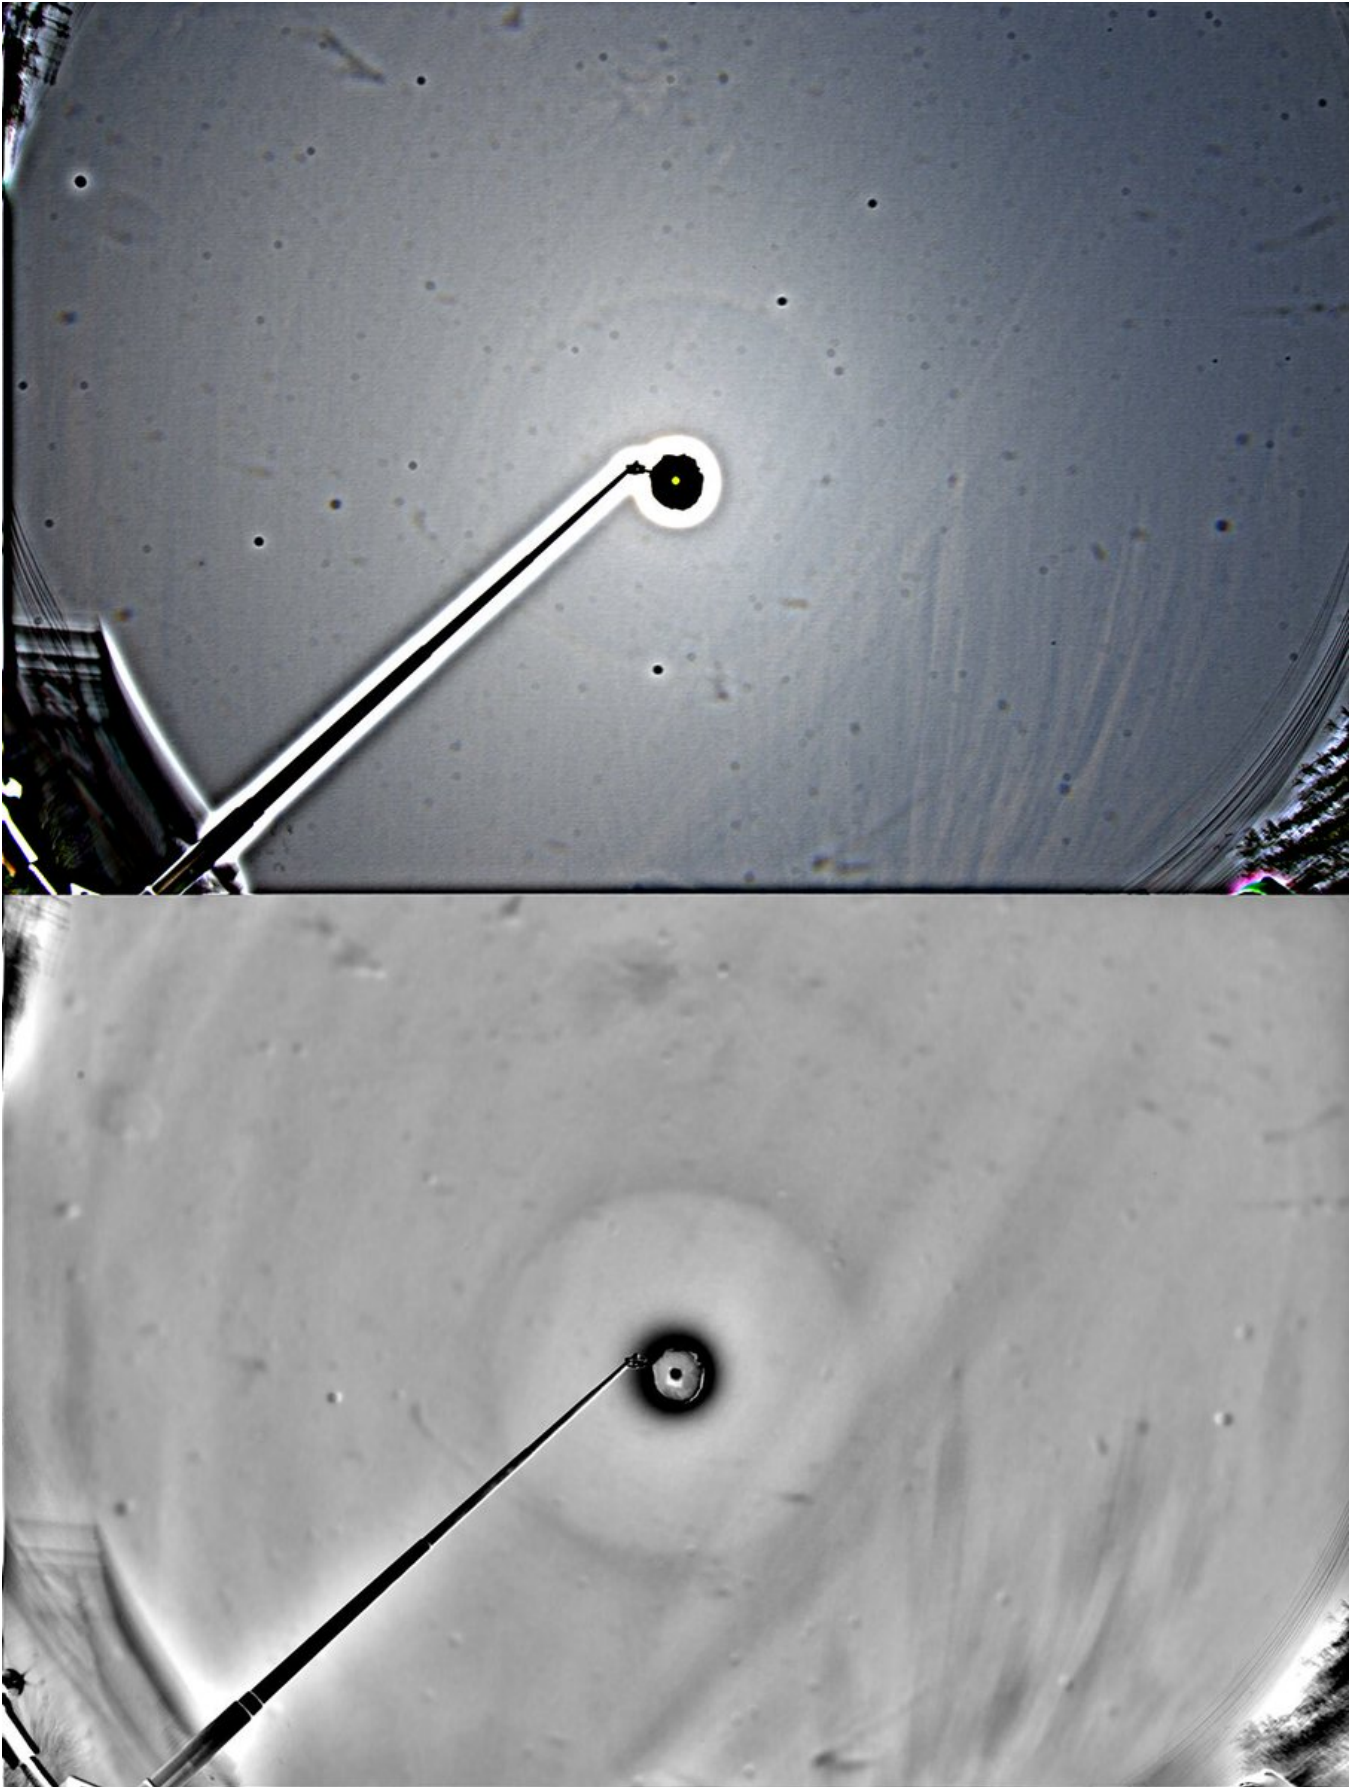

3/27 - 2025-07-05 13:17 UTC

The third display, a monologue of tanarc, kept me waiting until 25 April. I caught it from this very small cirrus. 27 frames in the stack.

4/27 - 2025-07-05 13:17 UTC

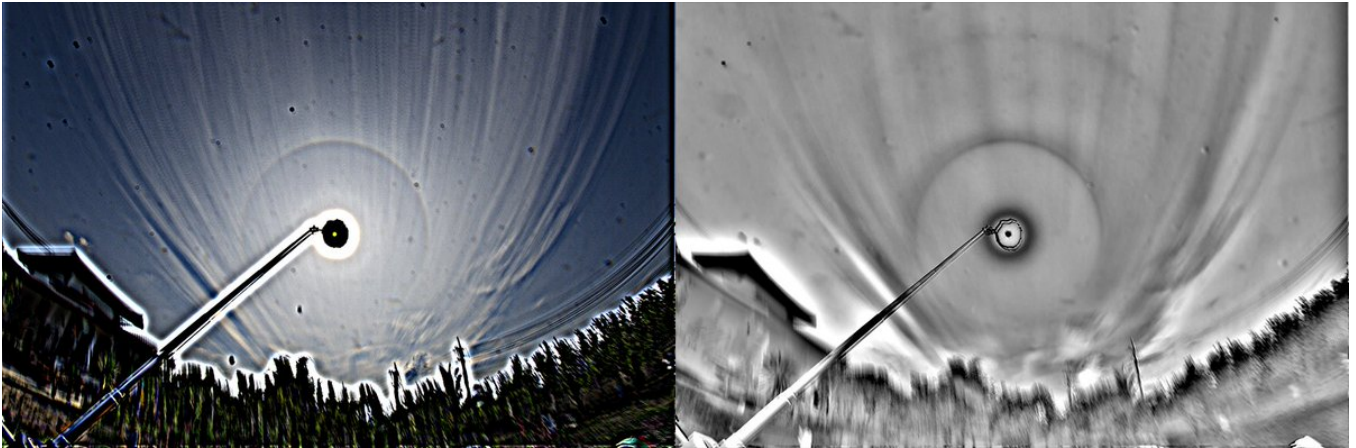

April's last display occurred on day 26. Nothing to party about this one either. 161 frame stack. I have a memory of having made also written notes of all displays, but can't find them. That's what happens when you mothball the stuff for too long.

5/27 - 2025-07-05 13:39 UTC

The first May display was on day 1, and it marked start of 14 uninterrupted days of halos. Also it

marked the start of odd radius displays, which totaled at the end of the month 13 days. I have labelled this as containing 9 and 24° halos, but not sure about the 9°. 100f stack.

6/27 - 2025-07-06 00:06 UTC

Found my notes, but incomplete, only until May 4. Notes say no halos on 26 April contrary to the stack I have for that day. The creation date for that image is for that day, so it's a bit mystery. And these notes also reveal there was display on 21 April – I actually remember it.

Chiang Mai 31.3. ---->

NEG until 8.4.

8.4. ** 22h, ph* (573f stack, 95 minutes, and nothing else but ph)

10.4. pil, 22ut, 22h (seen while at the immigration office. The pillar really brightened the day, got a photo of it)

11-17.4. NEG (all high clouds in Meteoblue 'grams have not panned out. On 17 was unannounced high cloud at the sunset, but no halo.)

18-19.4. NEG (these Mblue forecasted clouds panned out. There was high cloud at the sunset on both days. No halos, though, even if there were clouds in suitable positions in the sun direction.)

20.4. NEG (in the afternoon a little thunder and rain! After three weeks of scorching. Of course there were associated cirrus here and there, but no possible to see halo because sun area was blocked by cn.)

21.4. ph (the 4th successive day of cn cirri finally resulted in weak parheliion in the receding edge. The rain passed close by)

22.4. NEG (thunderstorm passed over but dropped only pitiful rookerful of rain. The cloud base was high and droplets evaporated. Radar showed heavy rain. Got anvil cirrus at the right distances momentarily, but no halo)

23.4. NEG (thunderstorm in the day and in the evening. Cn anvil was there again, but never suitably situated)

24.4. NEG (at sunset a lonely cirrus in the sky and some anvil cirrus in the cn clouds at the horizon. No good configurations for halos)

25.4. ** 22ut, 22h*, ph (ut from evaporating failed on turning into ice crystals, 22h was on robust similar cloud, but very weak only in stack. ph in the evening, visual. Change is afoot, no question about it)

26.4. NEG (2 or 3 cirrus wisps in the sun direction, a brightening in one at sunset, but not enough spotlight to make it pillar patch)

27.4. NEG (some cn cirrus present, no halo, no rain either)

28.4. NEG (same as above)

29.4. NEG (some cirrus)

30.4. NEG (some cirrus)

7/27 - 2025-07-06 00:14 UTC

Here is the remaining notes for May. This is in contradiction to my other notes about 14 uninterrupted days of halos from May 1 onwards as May 3 is NEG. I think the rest of the notes are lost for good. Can't find nothing on my computer or email or any other place.

1.5. ** 22h, 46h*, 24h* (an extensive anvil cirrus, didn't expect this, just proves that you need to photograph everything)

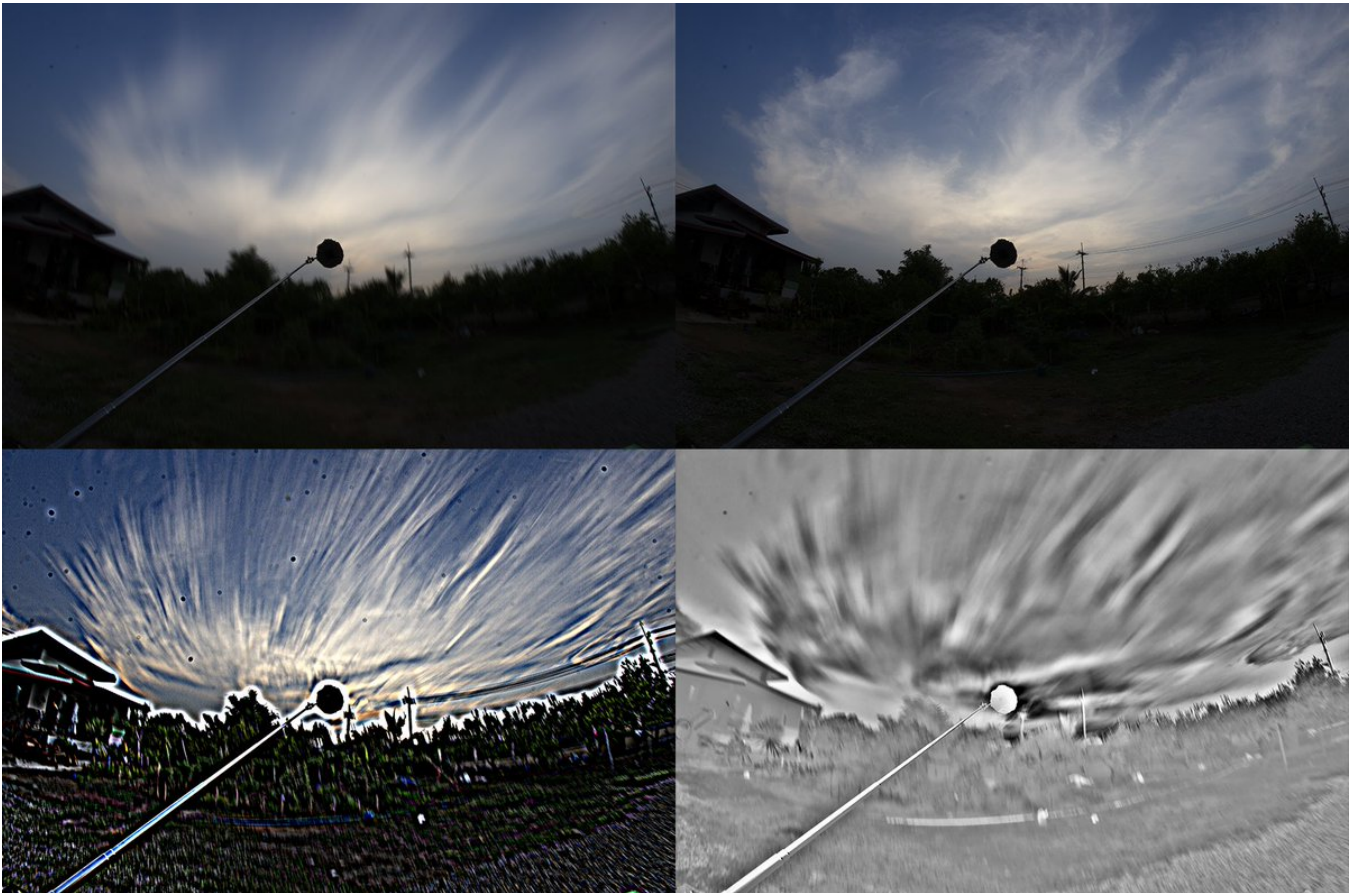

2.5. ph (was in the city the day, this one in Ban Kat when I came back. Anvil cirrus)

3.5. NEG (there was high cloud, for sure, and looked like plenty. But 490 stack and nothing. Did I stack just haze clouds? Can't believe I am so over the hill)

4.5. ** 22h, cza* (cn anvil cirrus, of course. There was some rain)

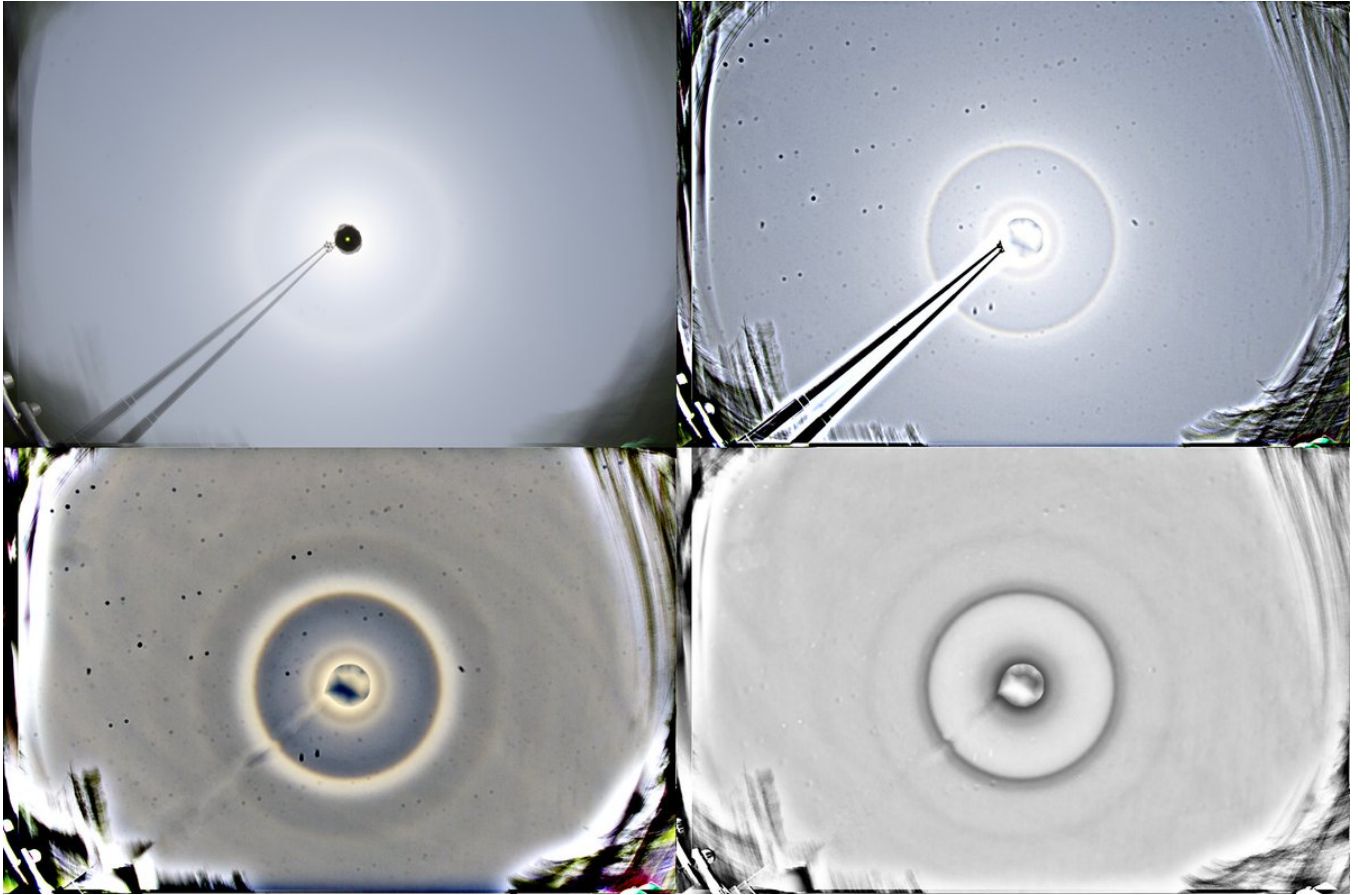

8/27 - 2025-07-06 09:22 UTC

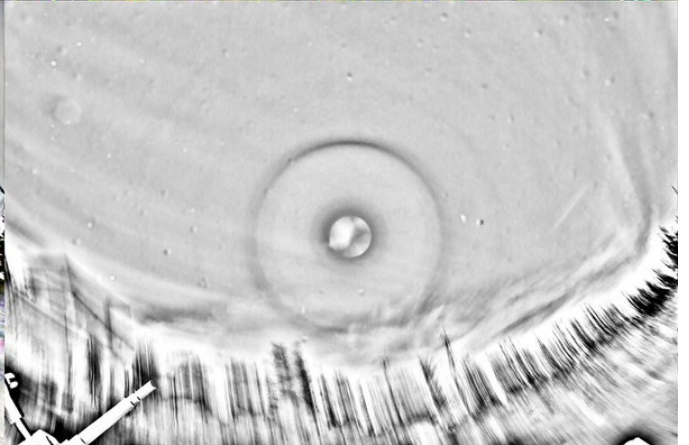

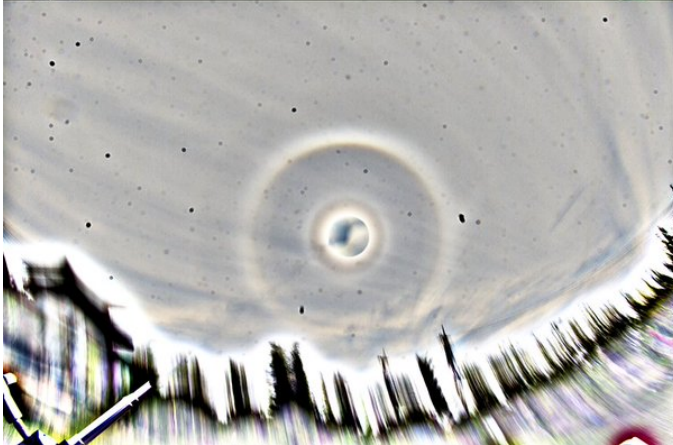

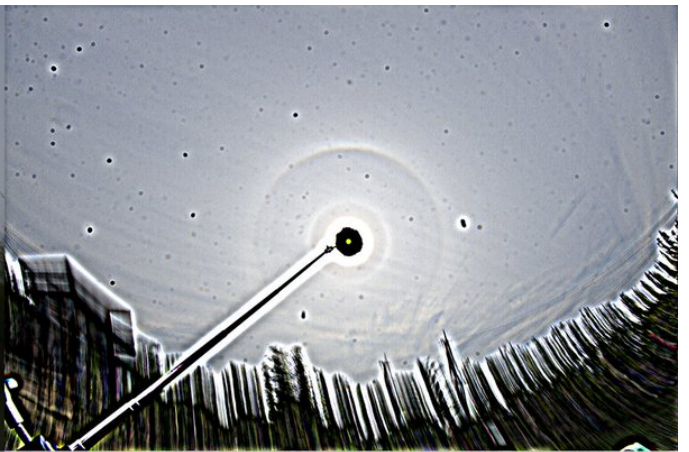

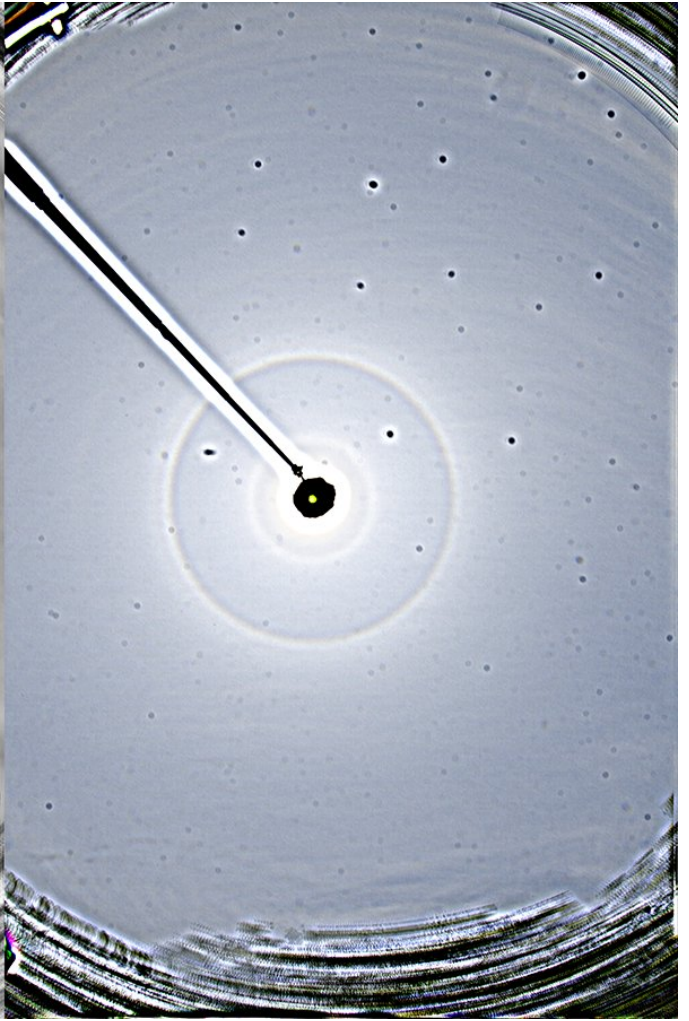

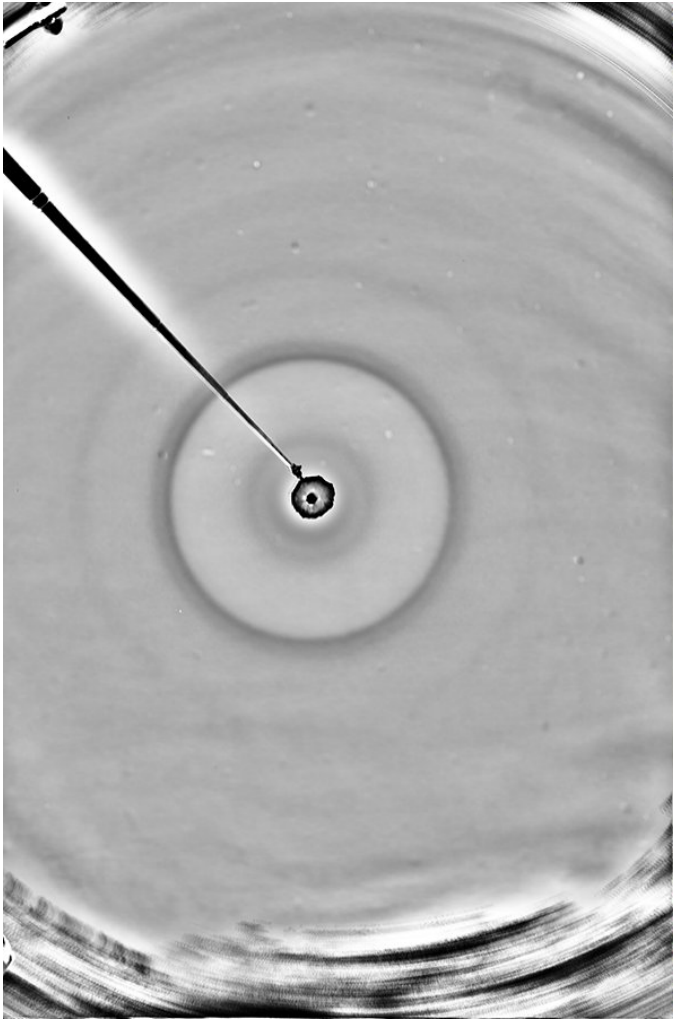

The display of 4 May, the last day of which I have notes of. 42 frames in the stack. As to rest of notes, now I know what happened. I had deleted them during space freeing operation on Gmail. Mistakes happen easily in these operations.

9/27 - 2025-07-06 09:52 UTC

8 May, odd radii. 1) 1104-1345 800f 2) 1154-1211 100f 3) 1510-1600 300f. Meteoblue satellite animation of the arrival of high cloud. There was thunderstorms in the east.

[video: 1941797460667465804-GvKmEGIW0AATQTr.mp4]

10/27 - 2025-07-06 10:04 UTC

9 May. 9, 20, 24, 35°. By the sharpness of 20°, looks like crystals were column oriented.

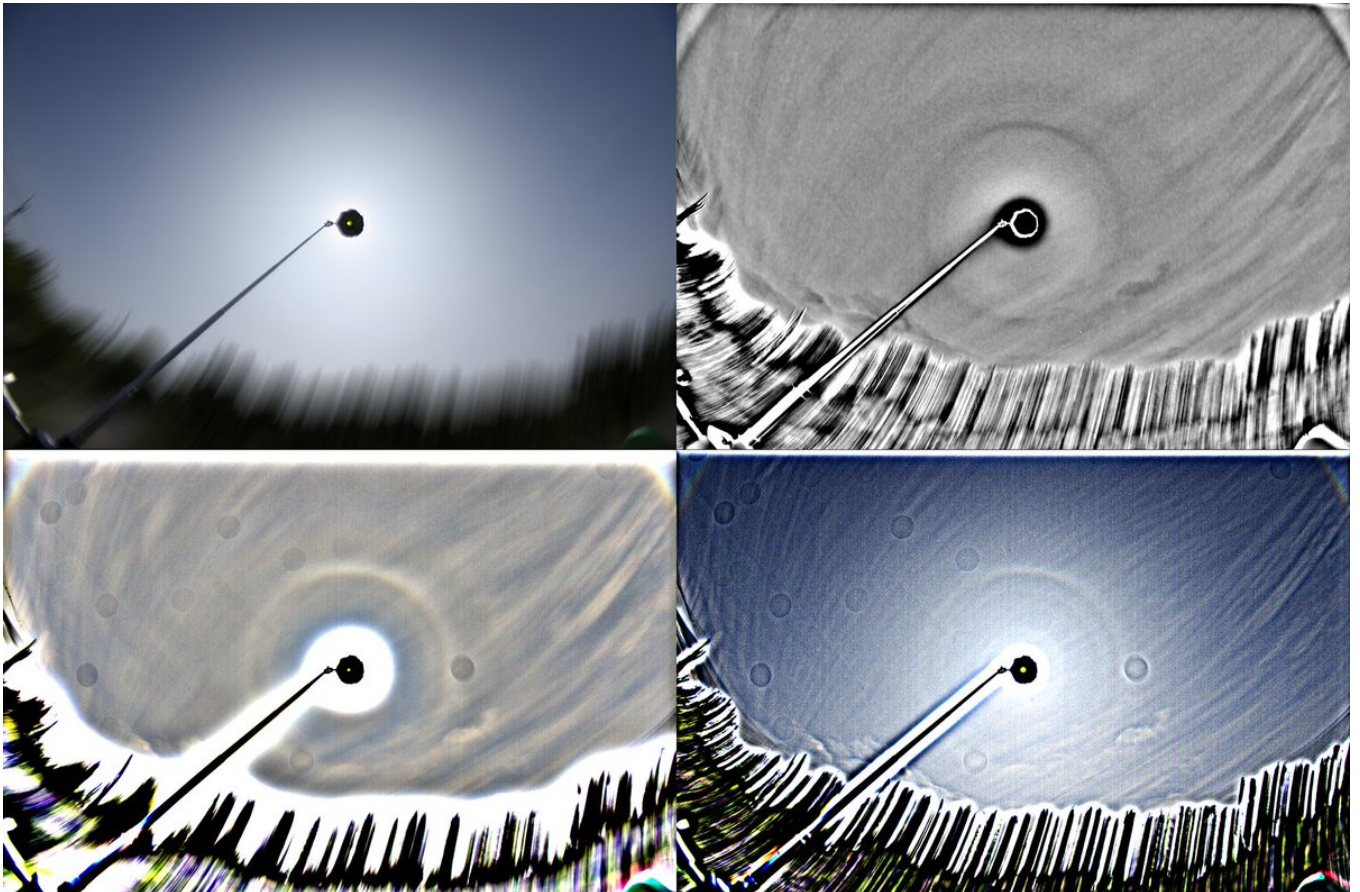

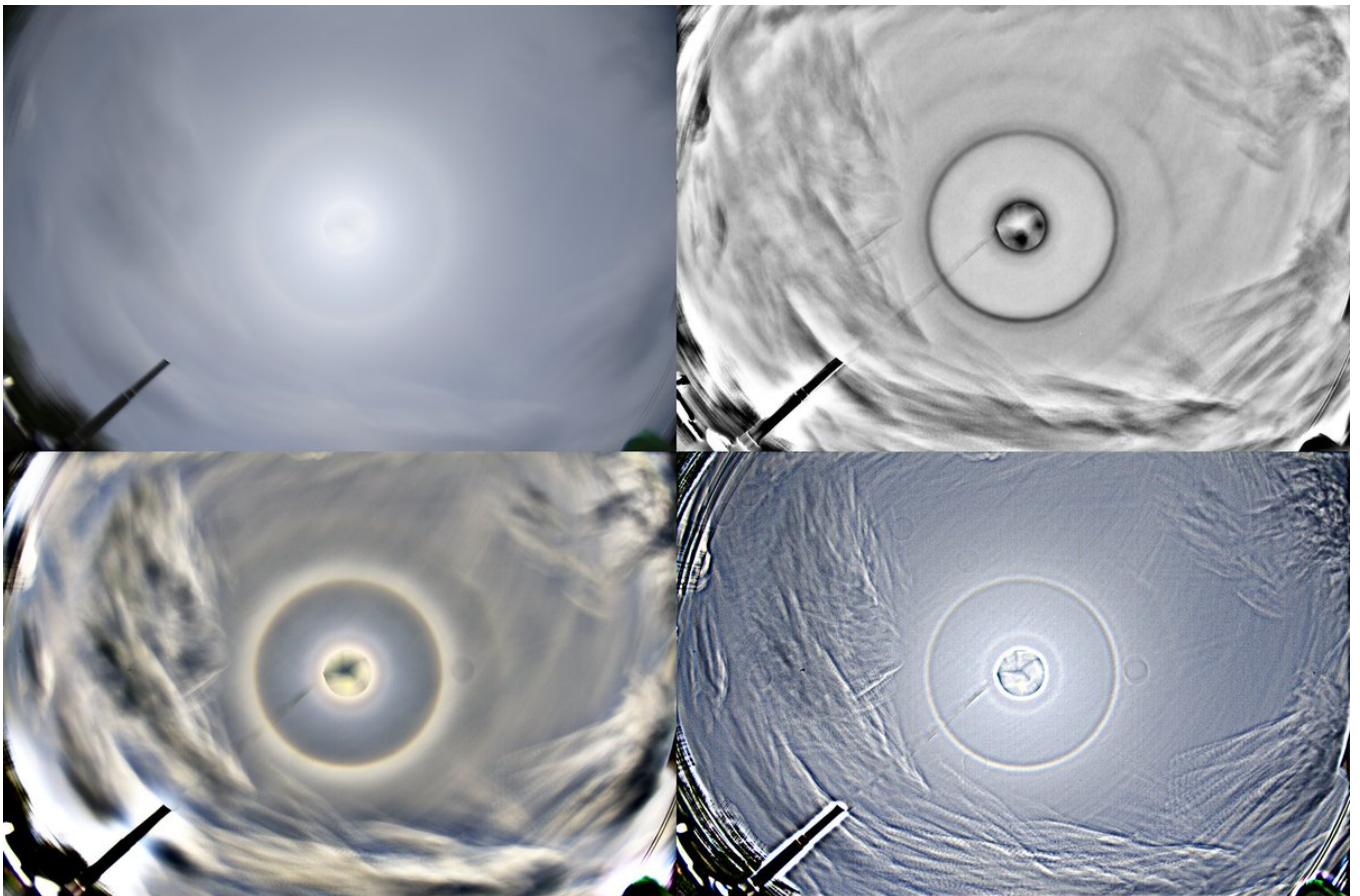

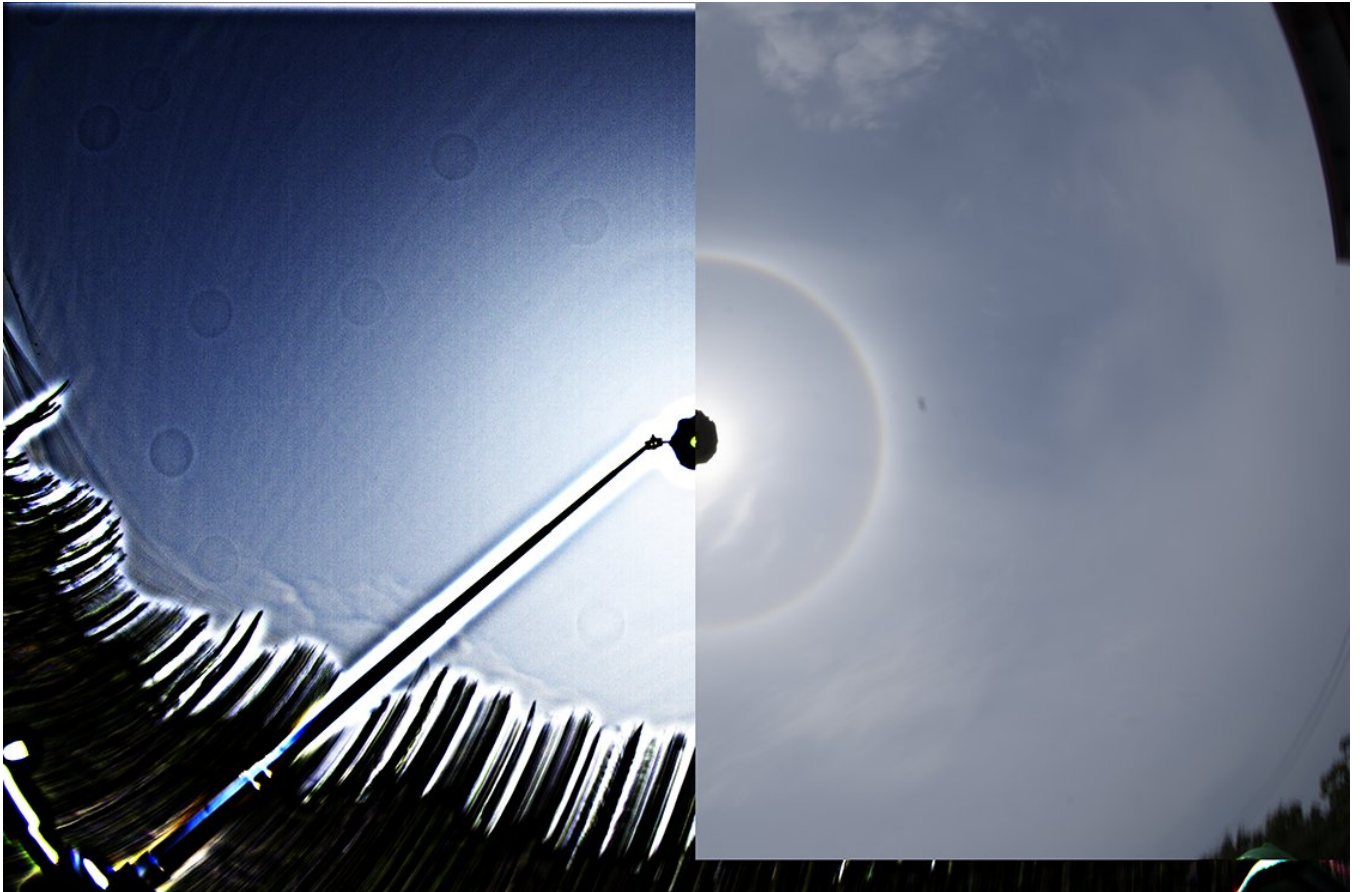

11/27 - 2025-07-06 10:13 UTC

10 May. 9, 18, 20, 23, 24, 35°. 1) 0916-1017 363f 2) comparison with 22h to show that 0916-1017 the main ring was 23h 3) 1152-1203 65f Photo interval 10s, same also 9 May.

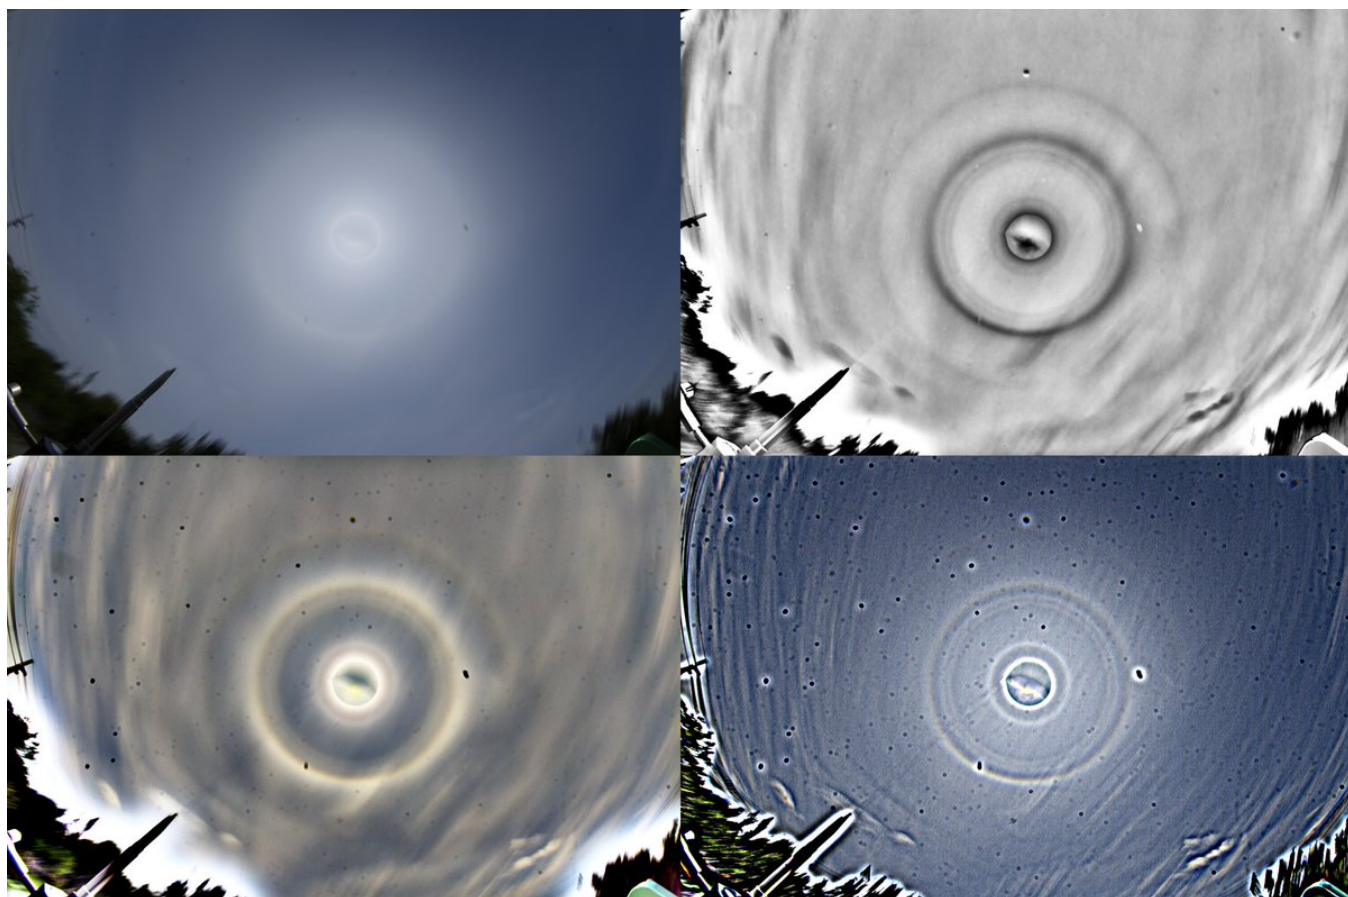

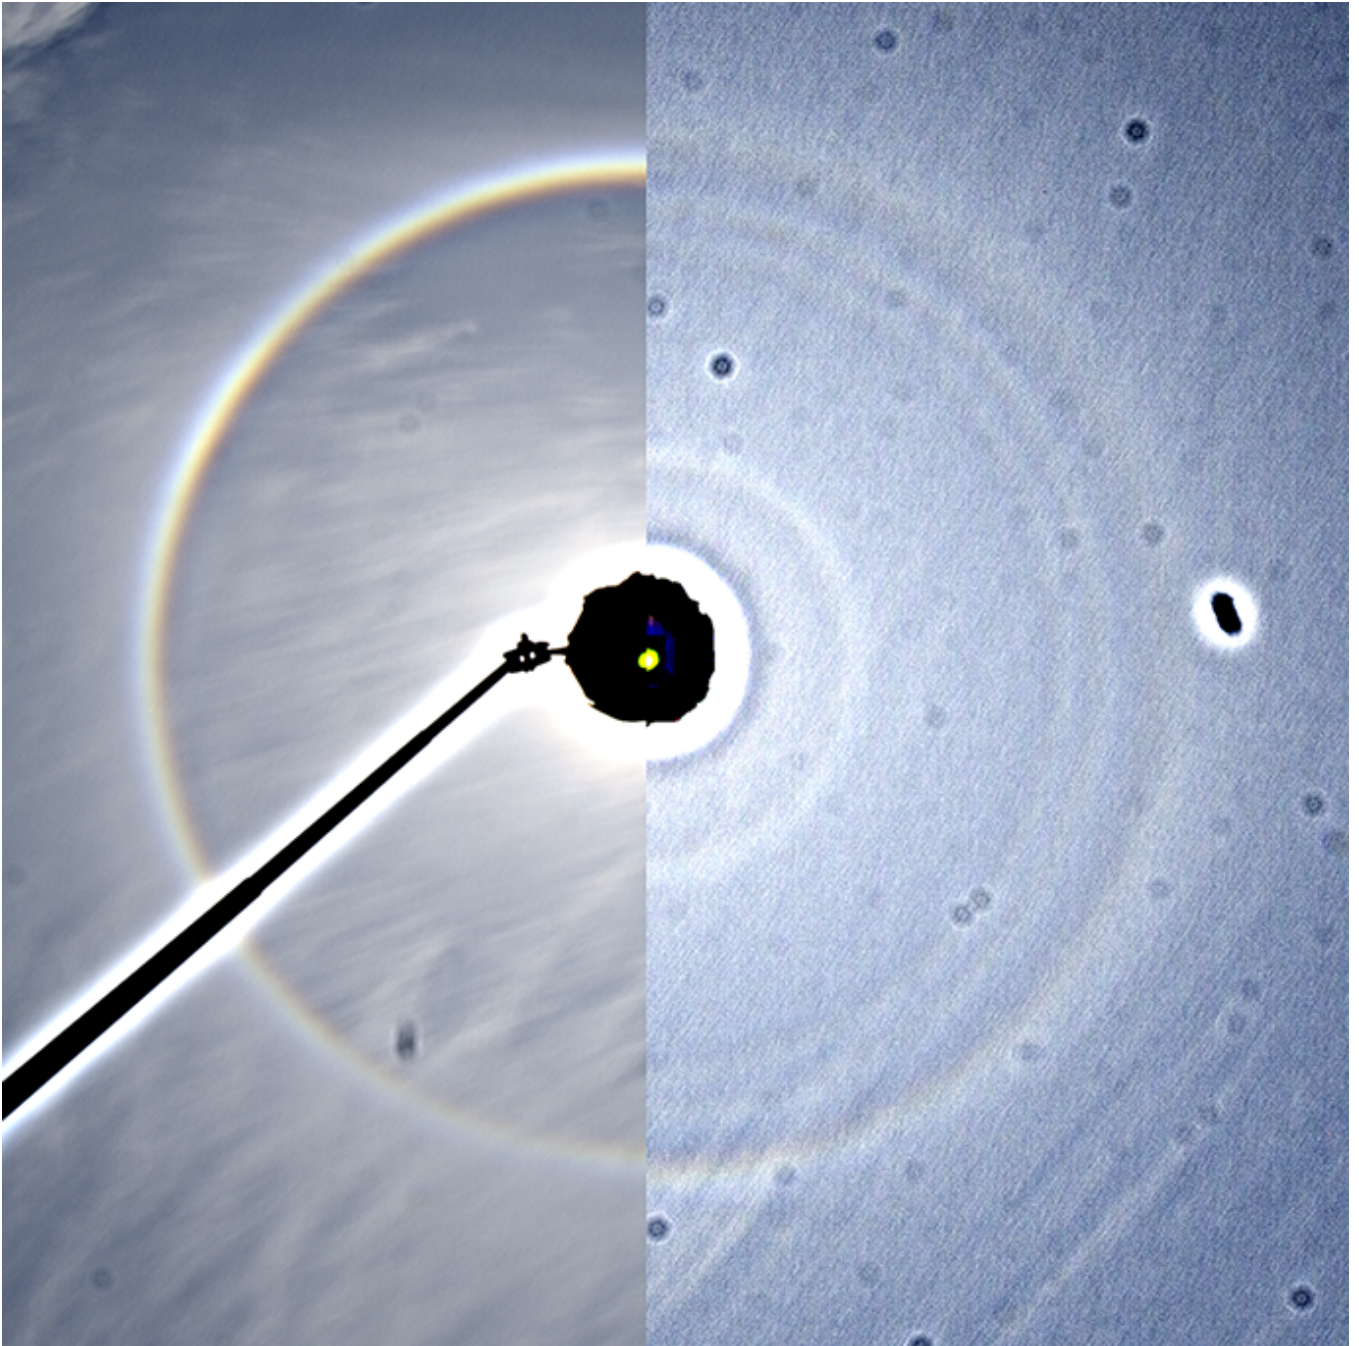

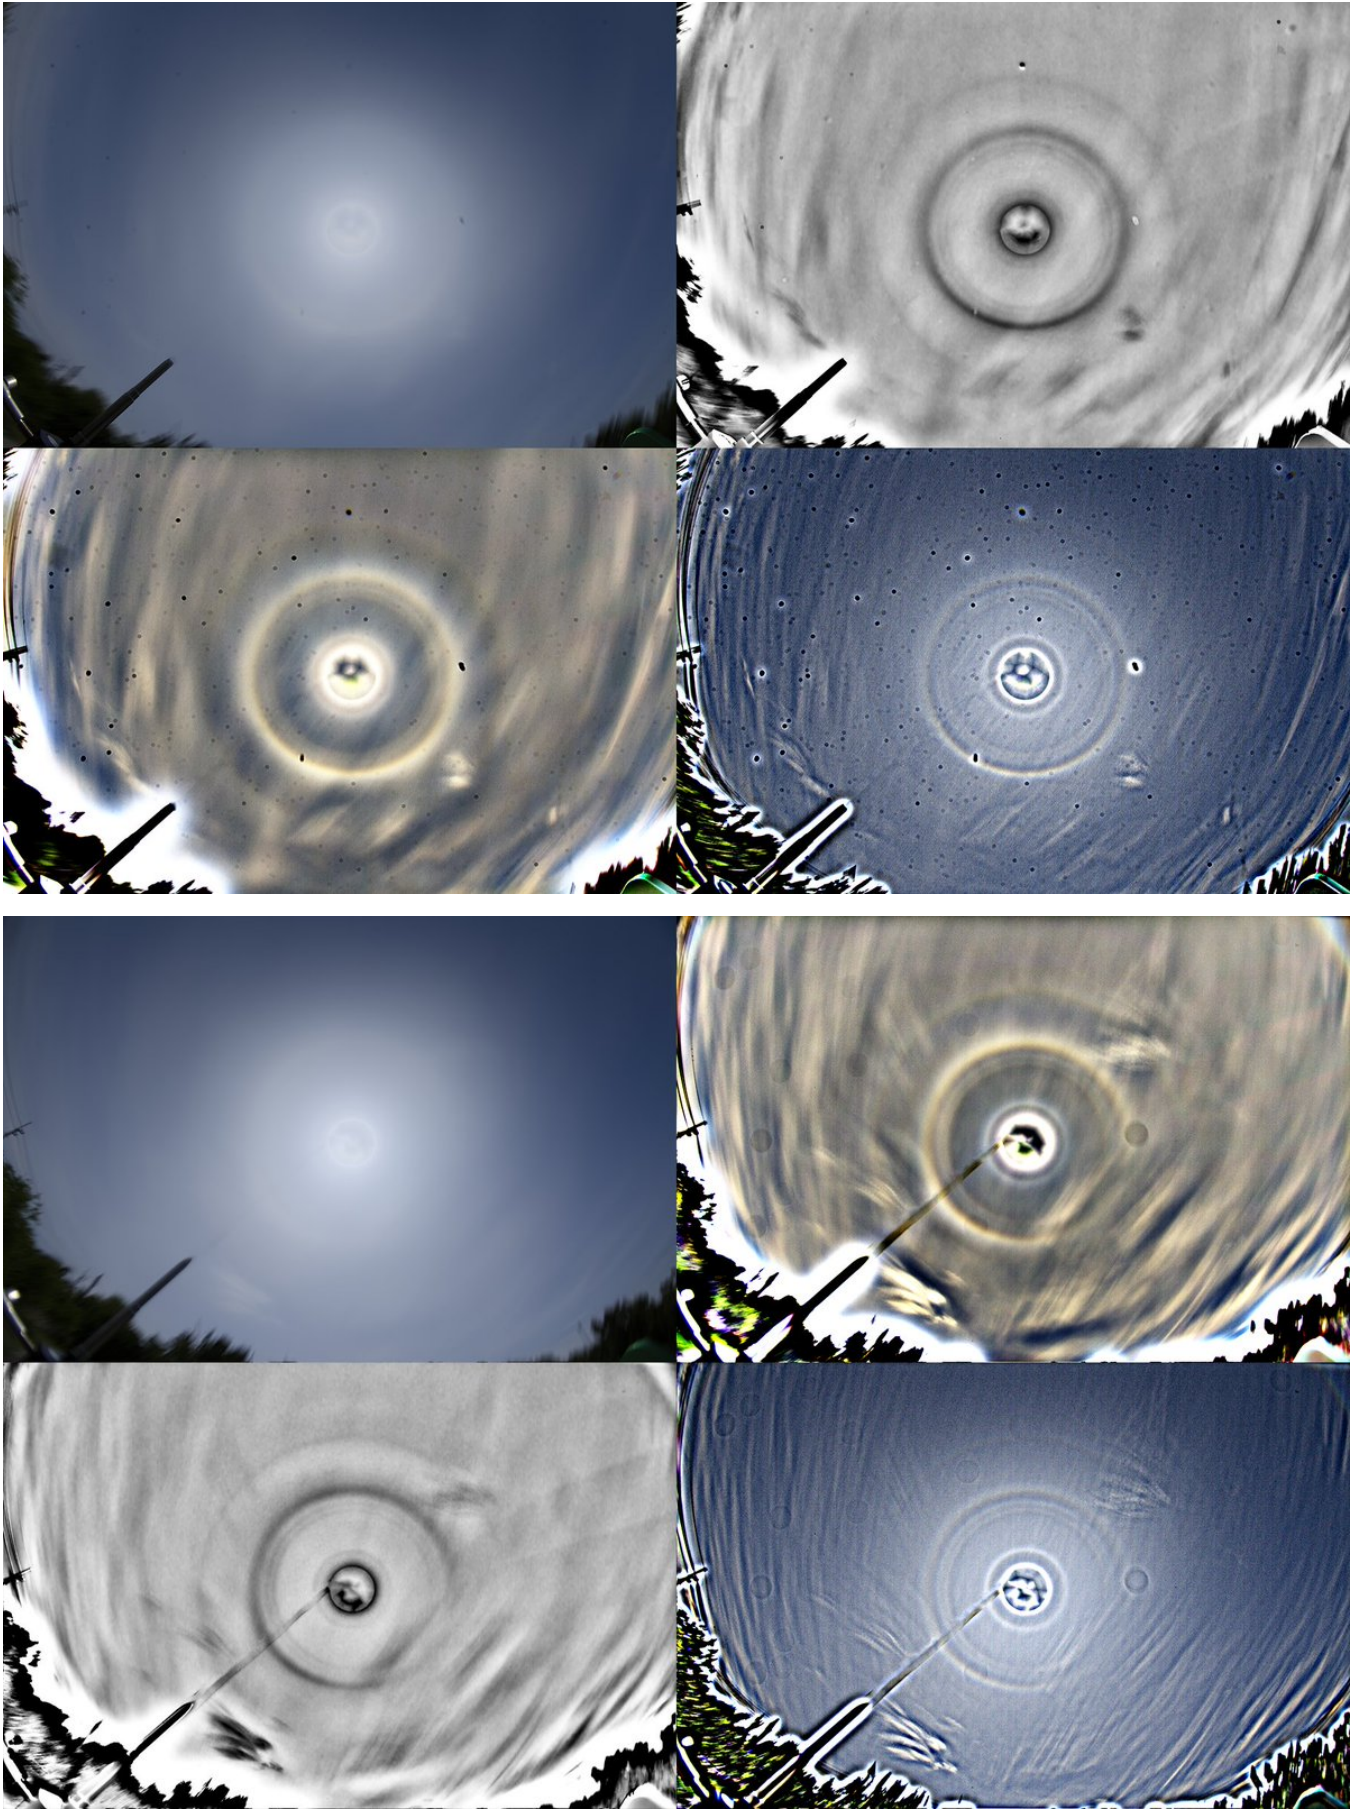

12/27 - 2025-07-06 10:31 UTC

11 May. 9, 18, 20, 23, 35°. 1) 1049-1103 84f 2) size comparison 3) 1103-1117 85f 4) 1152-1203 65f.

There is probably also 24° halo, but can't see it separately.

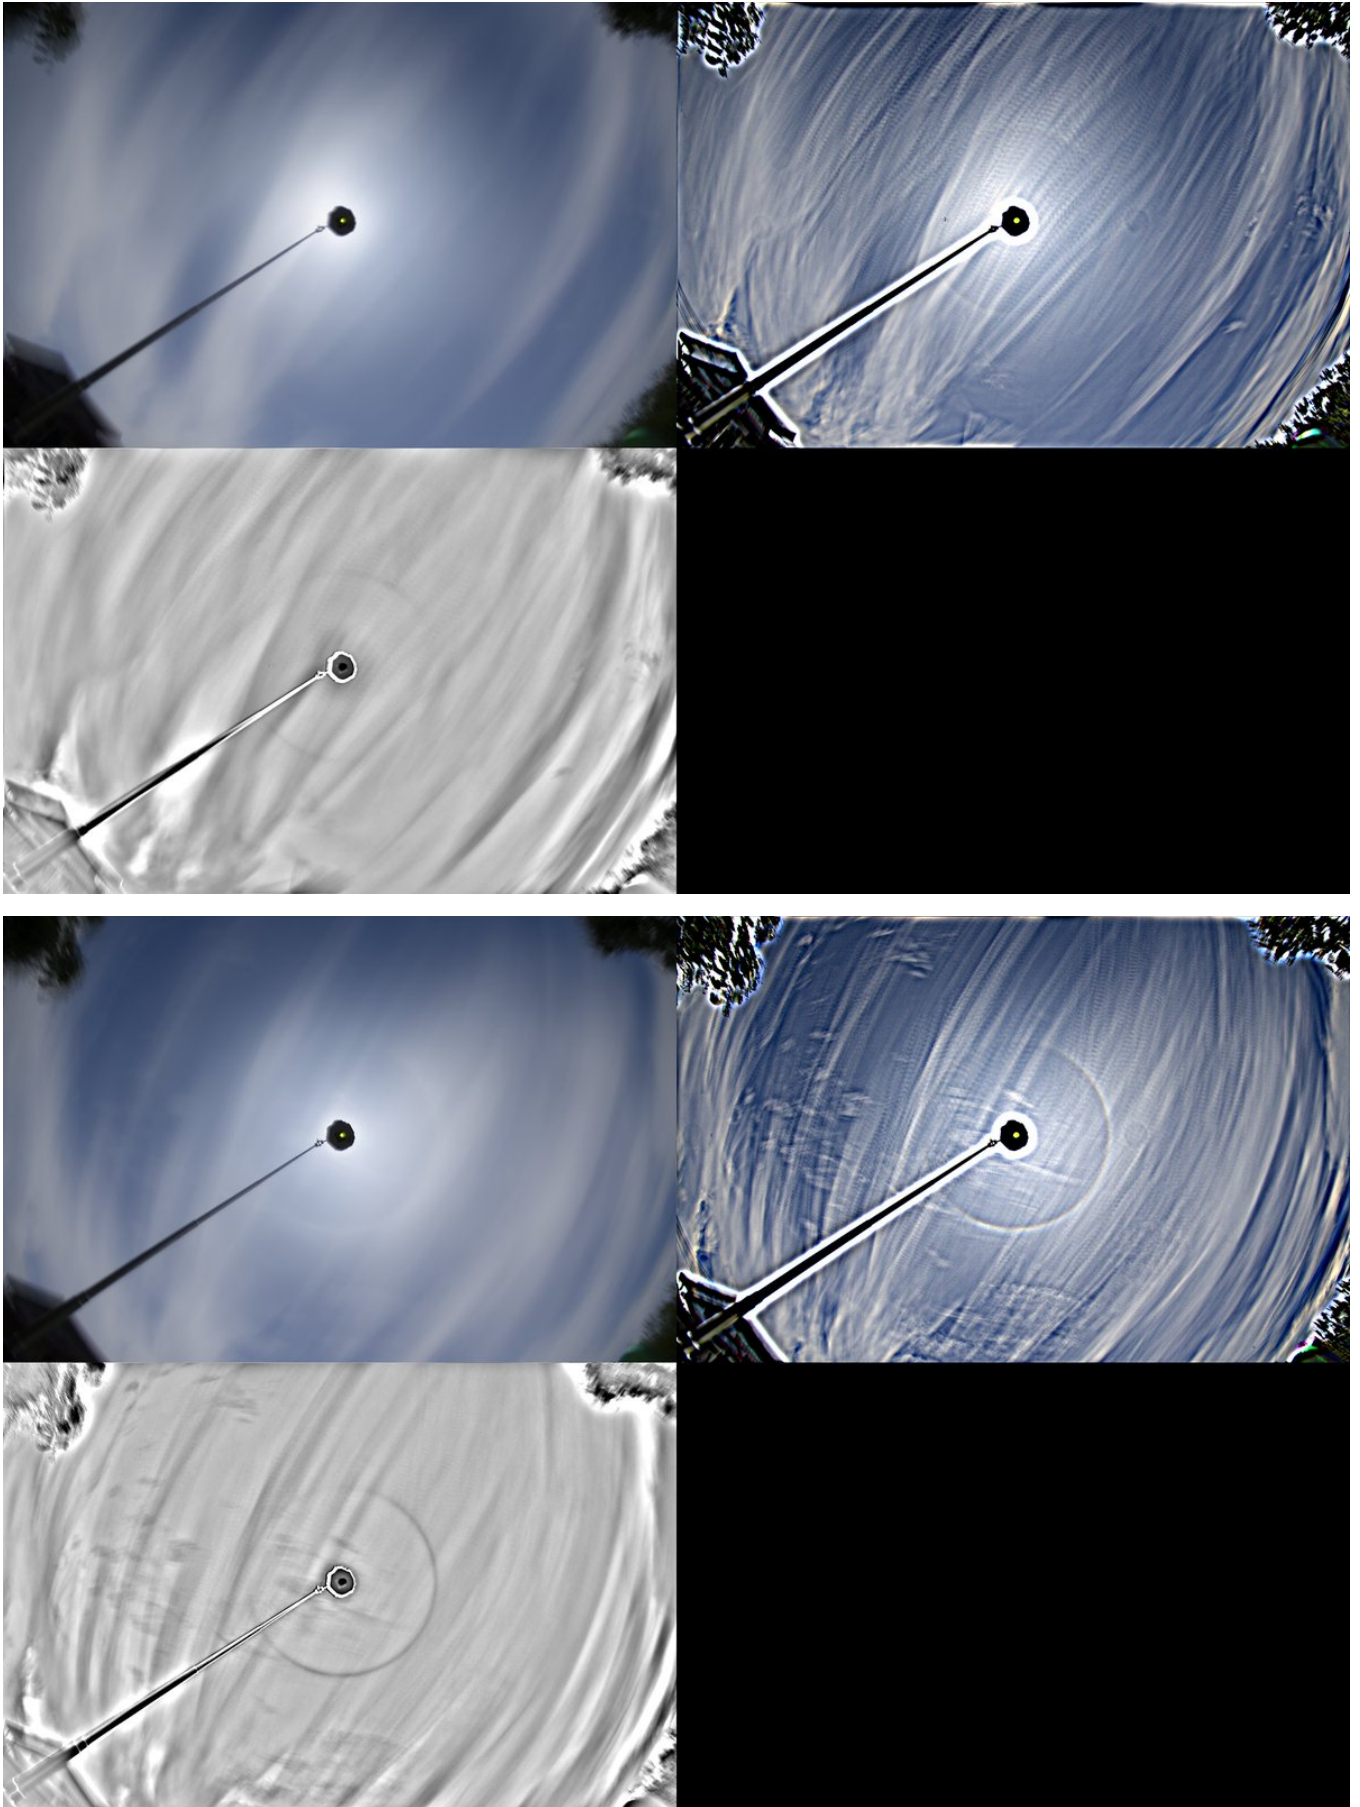

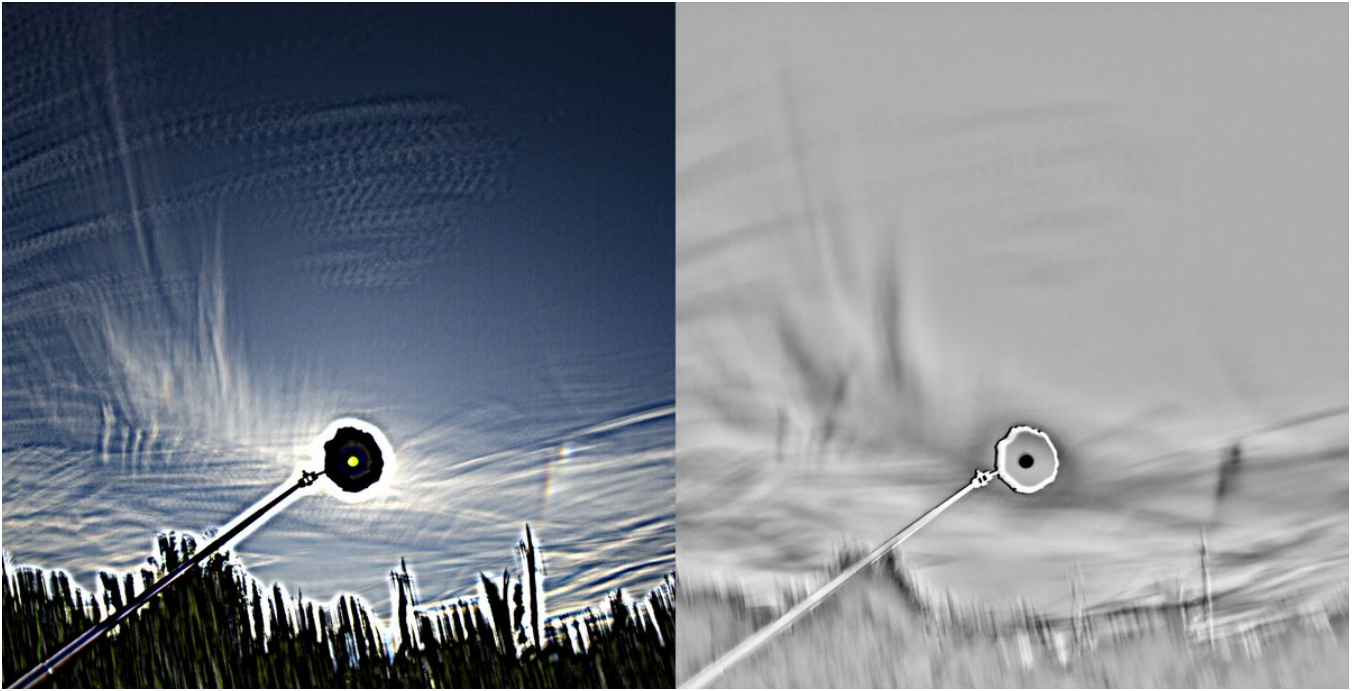

13/27 - 2025-07-06 12:42 UTC

12 May. No odd radii. 55 and 63 frames in the stacks, interval 10s.

14/27 - 2025-07-06 12:49 UTC

13 May. Late afternoon. Parhelion and segment of 22° halo. Possibly Lowitz involved. 91f 10s.

15/27 - 2025-07-06 12:51 UTC

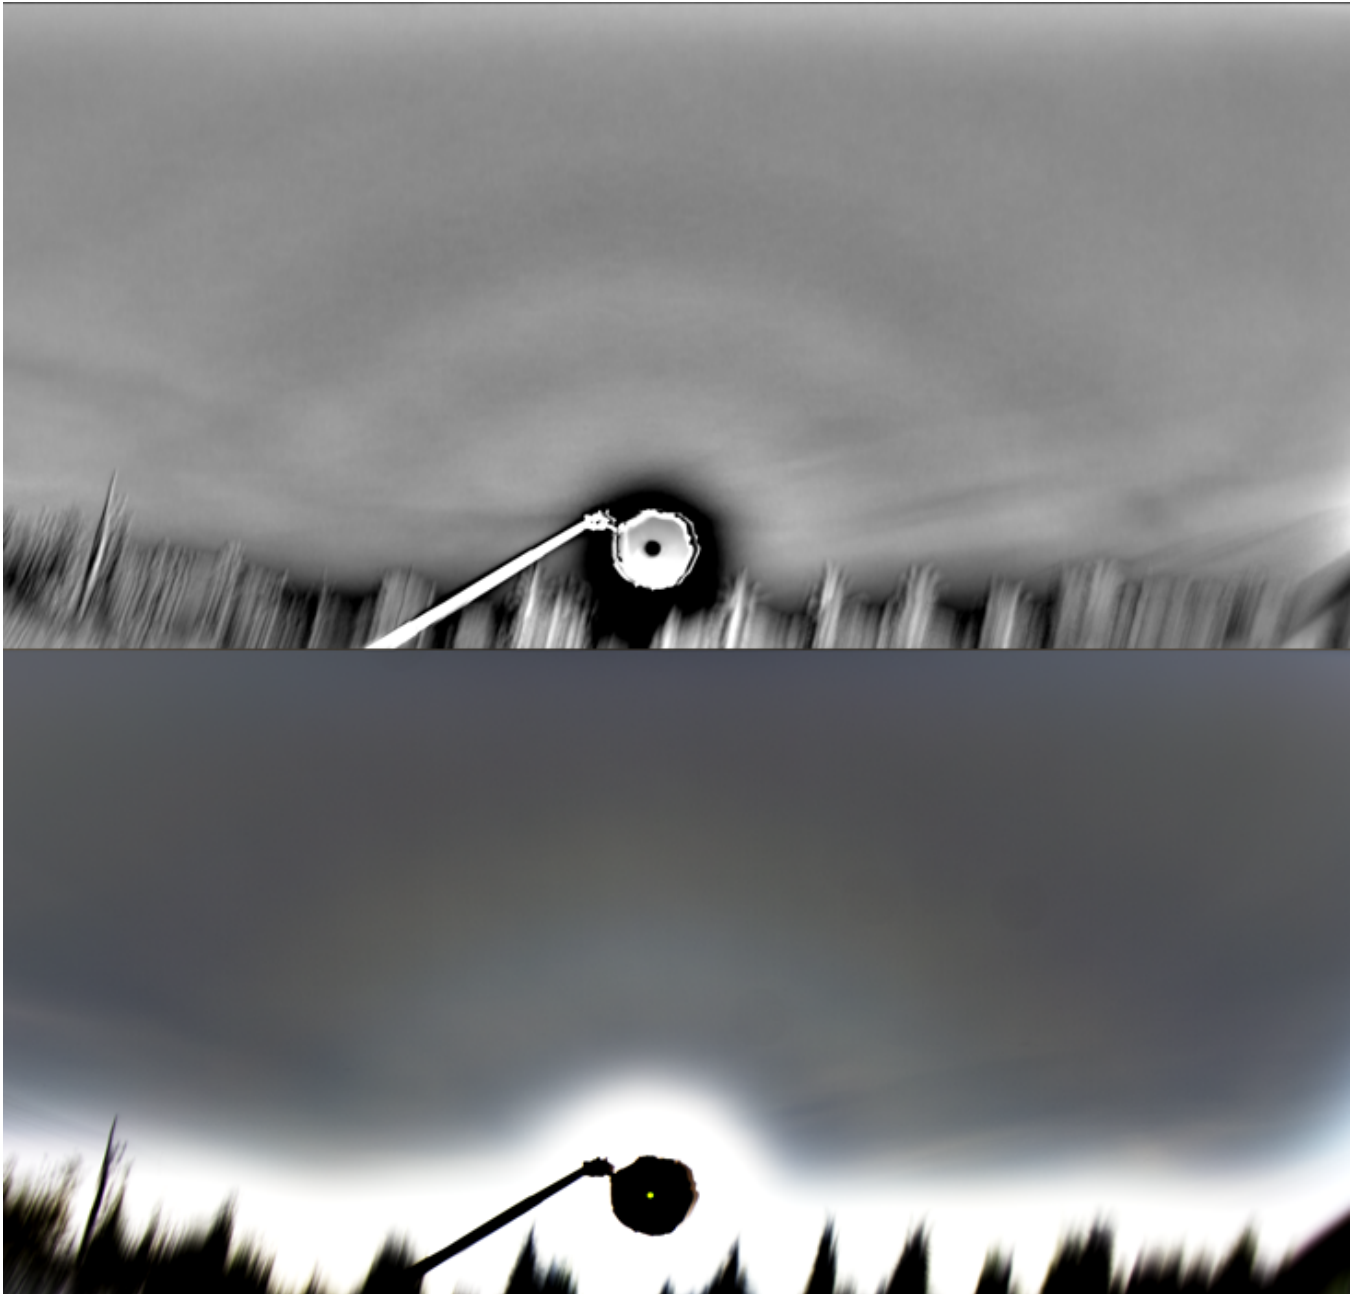

14 May. In the morning. 22h, tanarc and looks like also 46h, too. 57f 10s.

16/27 - 2025-07-06 12:57 UTC

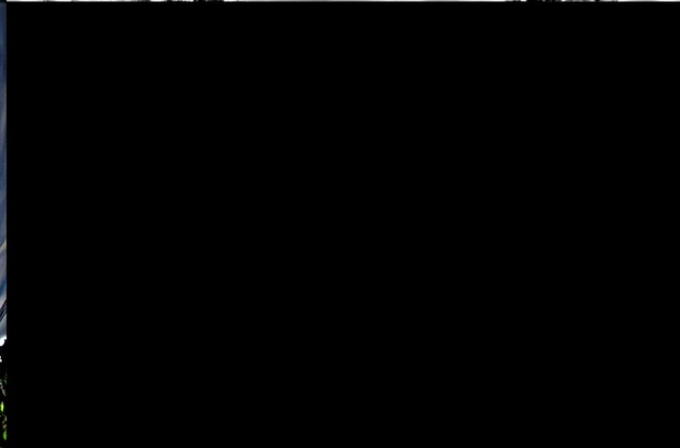

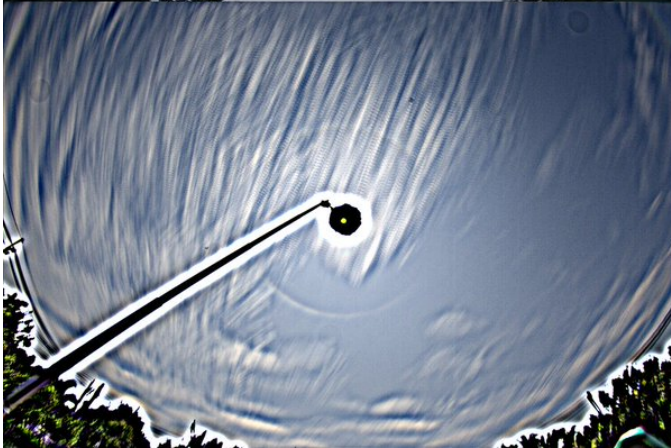

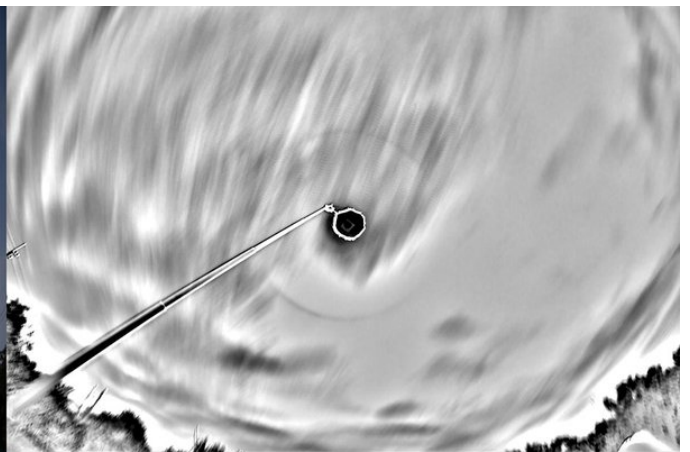

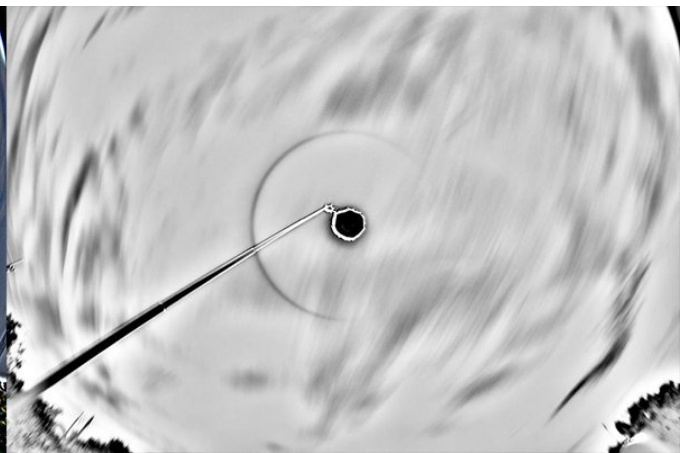

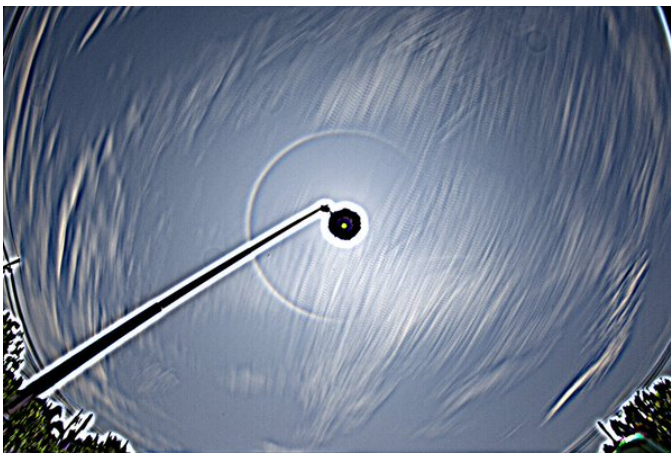

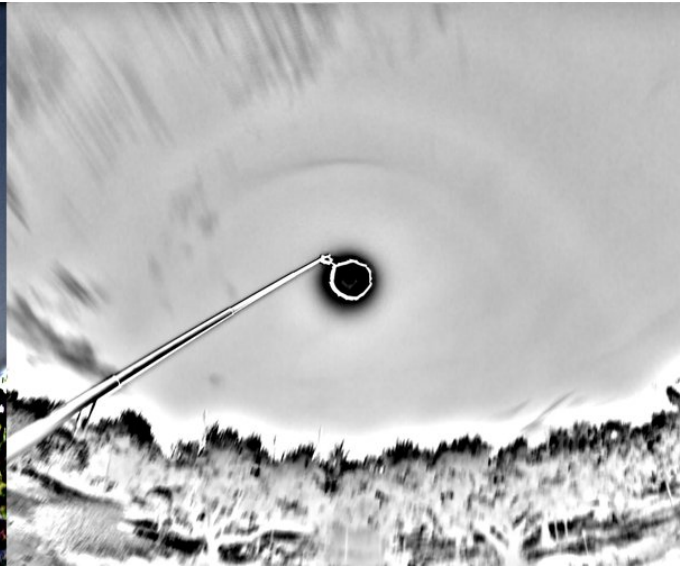

16 May. An odd one out. Faint and very broad ring of curious radii materialized from the morning stack. 239f 10s. I got even better case earlier in the island of Ko Samui. I'll delve into the Samui period (about 2½ months) once I am finished with Chiang Mai.

17/27 - 2025-07-06 13:01 UTC

18 May. 36, 52, 45 frames stacks, at 0858-0904, 1047-1056, 1122-1129, respectively. Interval 10s.

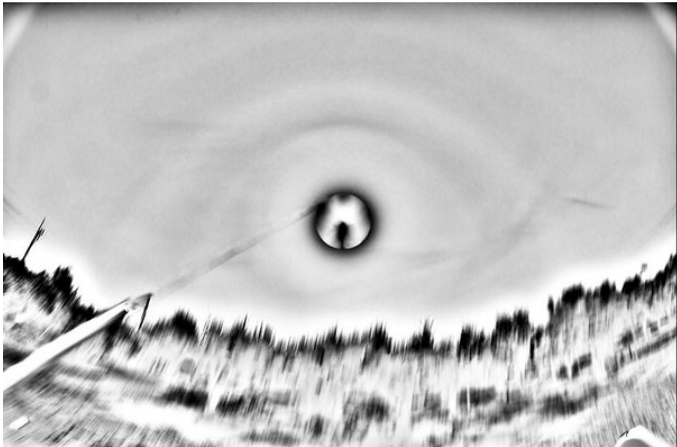

18/27 - 2025-07-06 13:05 UTC

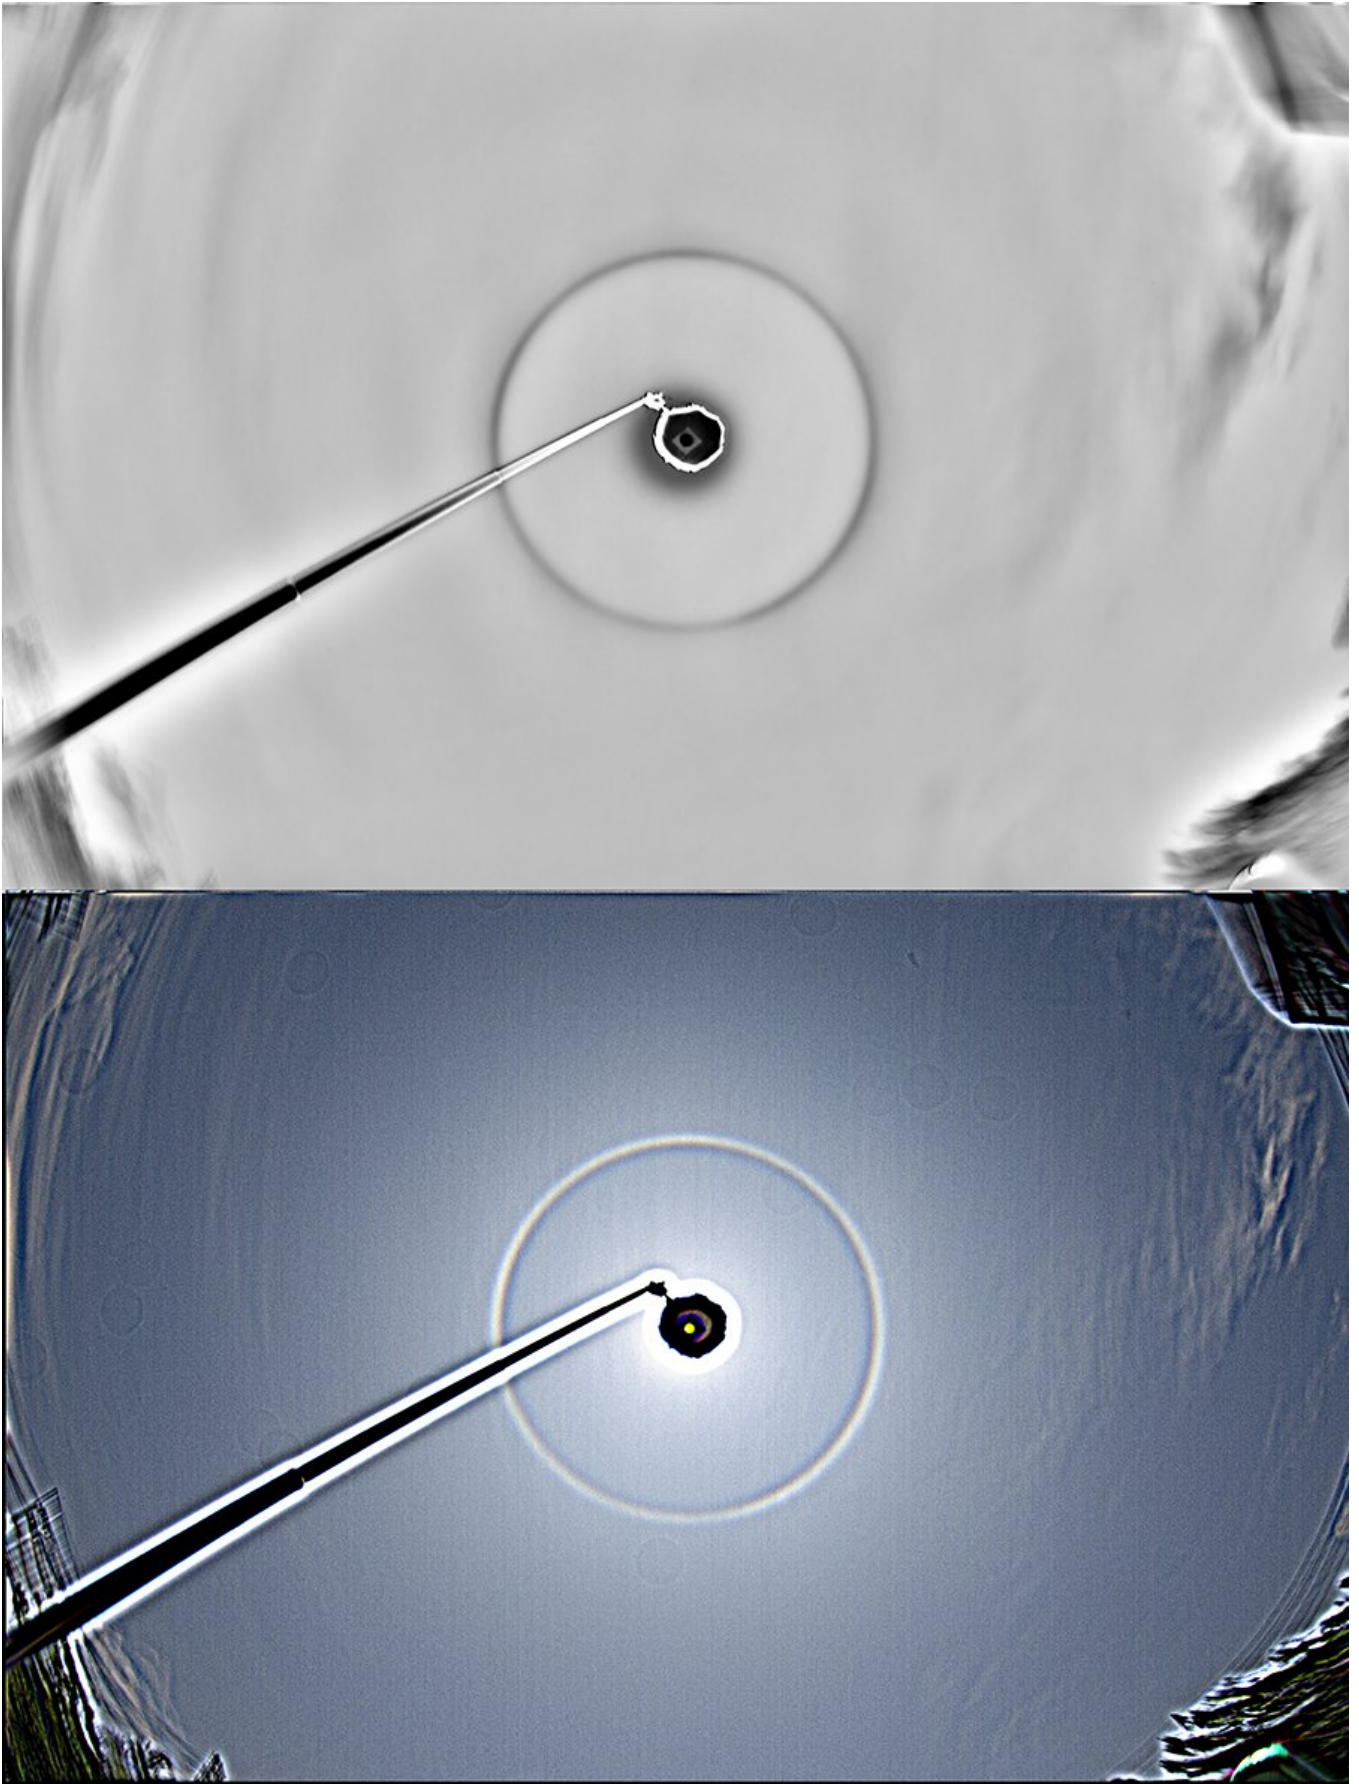

21 May. Parhelion, 22h in Cn anvil in the late afternoon. 17f 10s.

19/27 - 2025-07-06 13:15 UTC

22 May. Odd radii back in business. In the morning 18 and 23° plate arcs (0829-0845 100f 10s). At midday just 22°, probably chiefly contributed by tanarc judging by the sharpness of it (1120-1146 150f 10s).

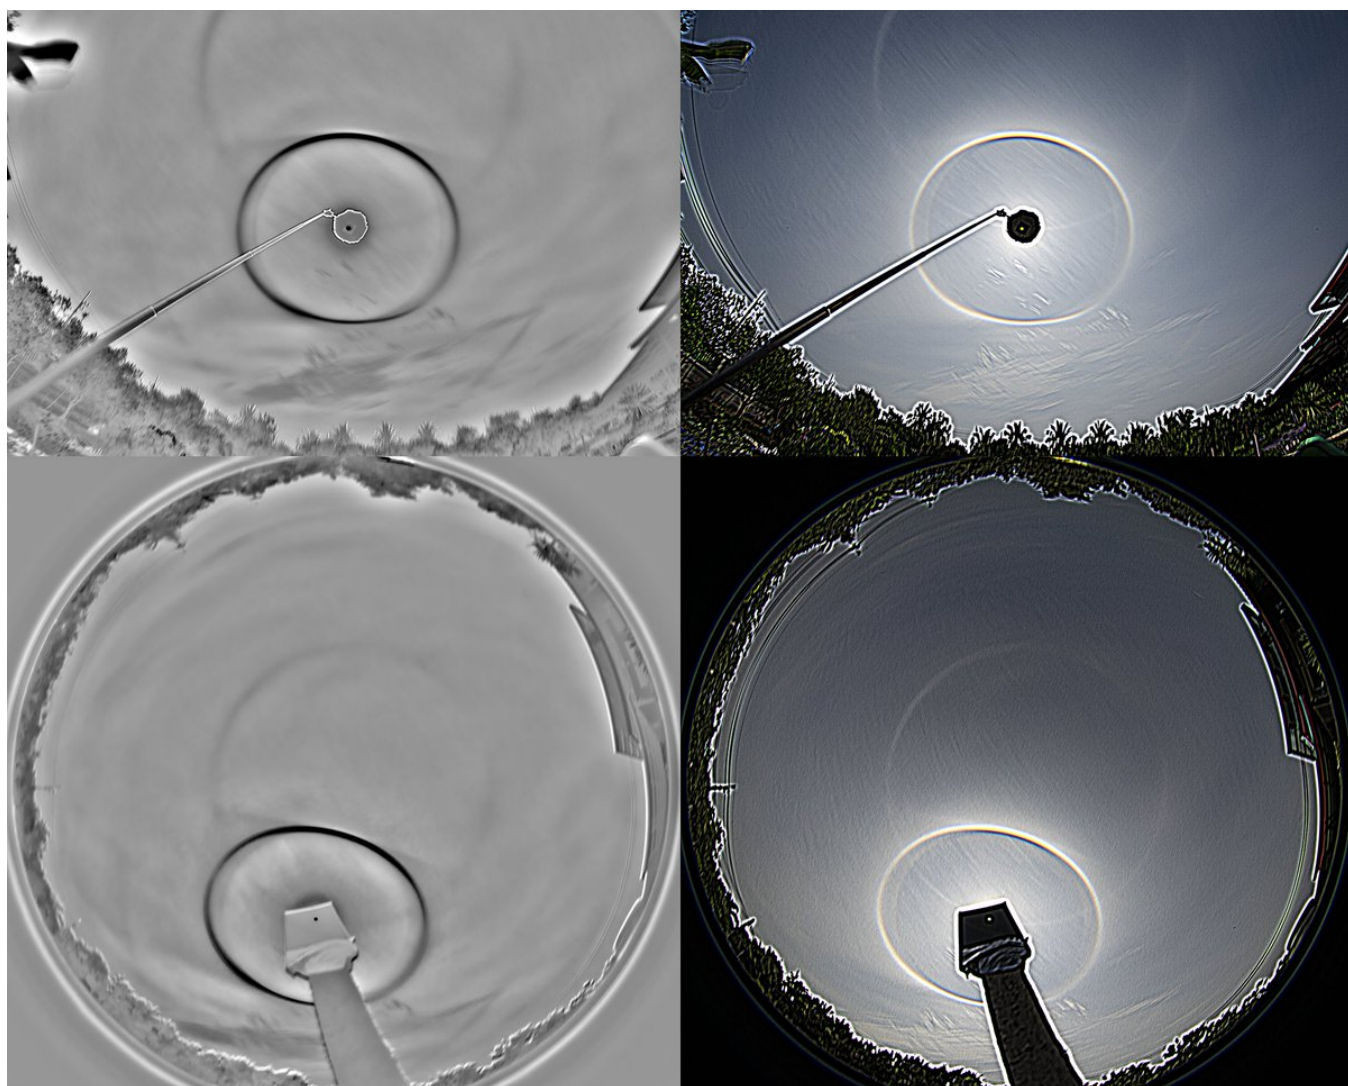

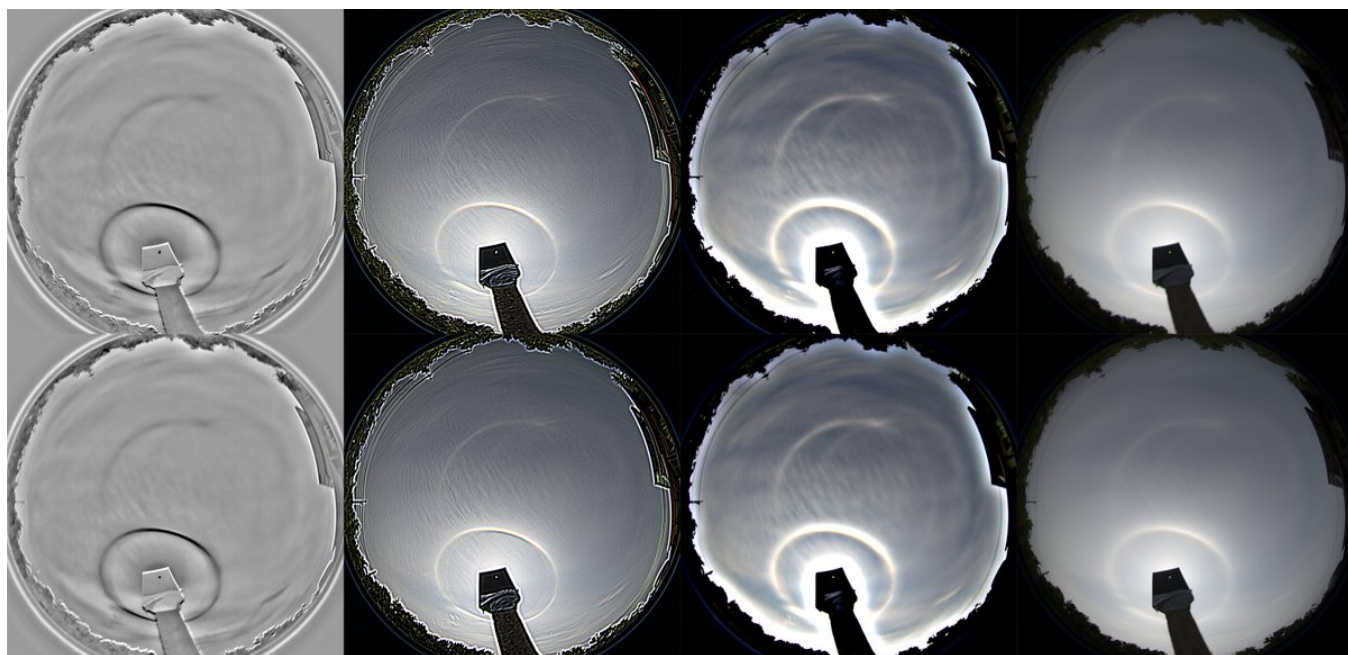

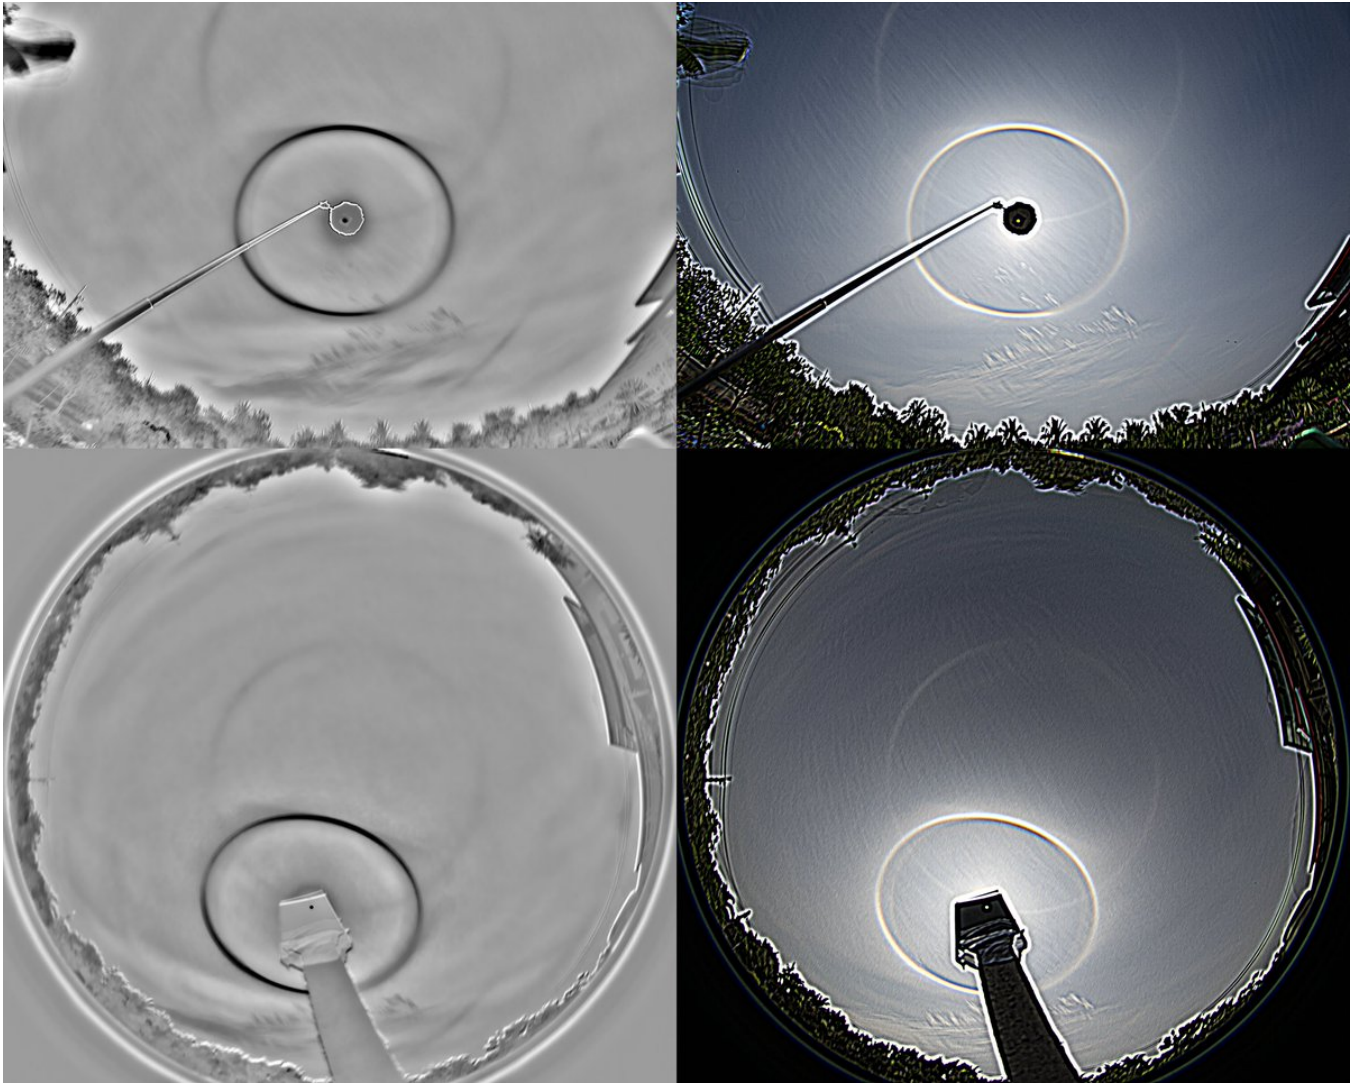

20/27 - 2025-07-06 13:30 UTC

23 May. All-sky display with Wegener, anthelion, infralatare and upper Parry. 1) comparing frame and

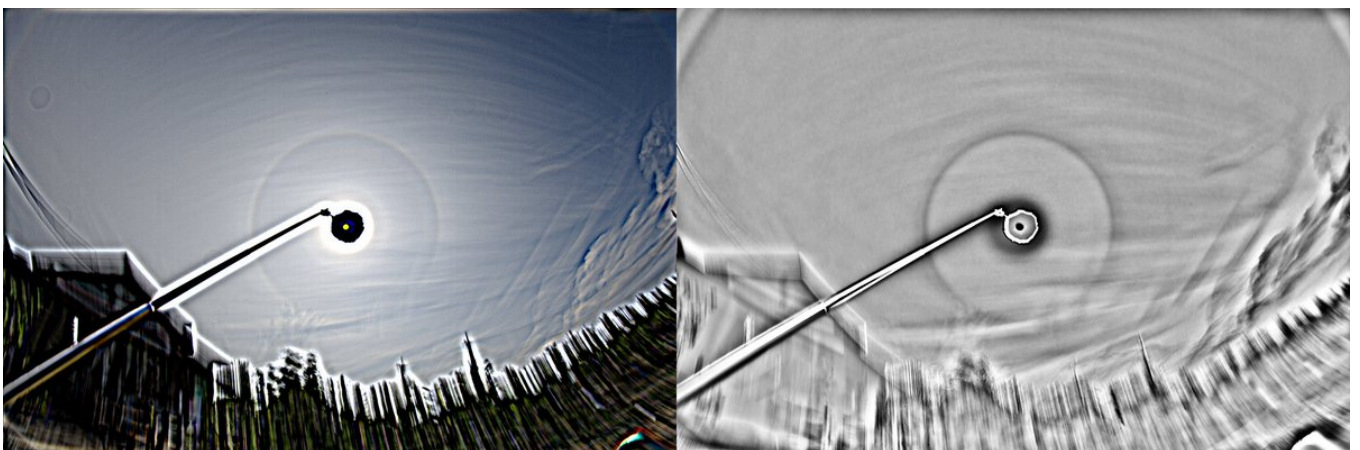

sun aligned stacks. 27f 10s. 2) parallel stacks with Nikon D7000 and Canon 80D. Canon sucks.

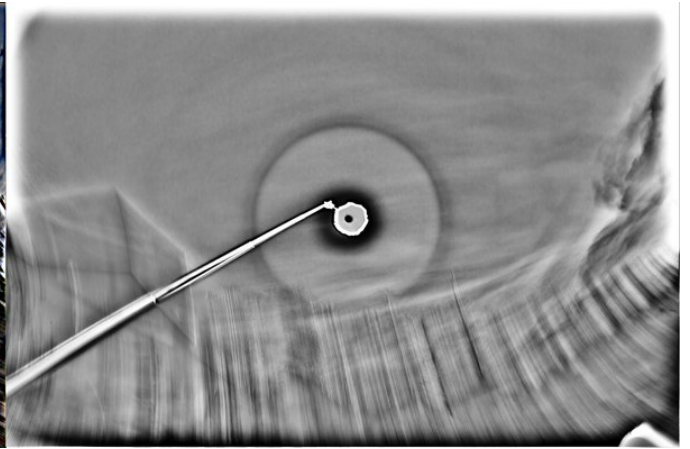

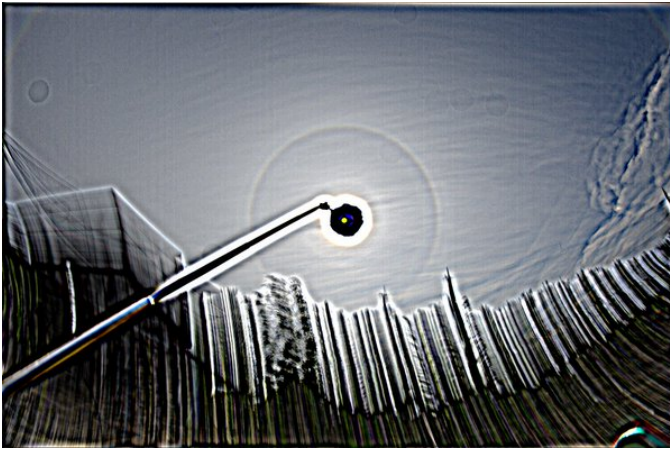

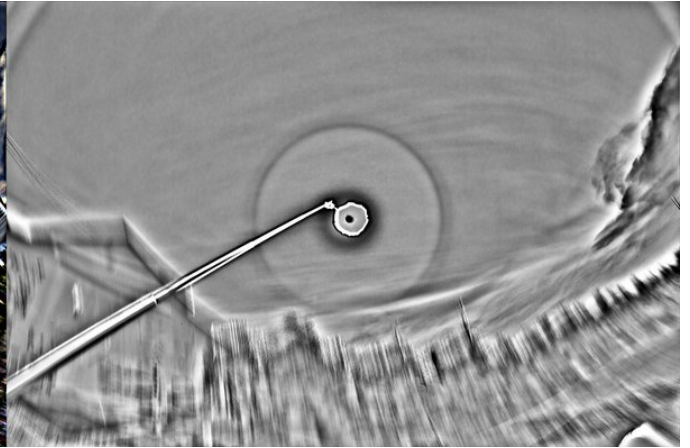

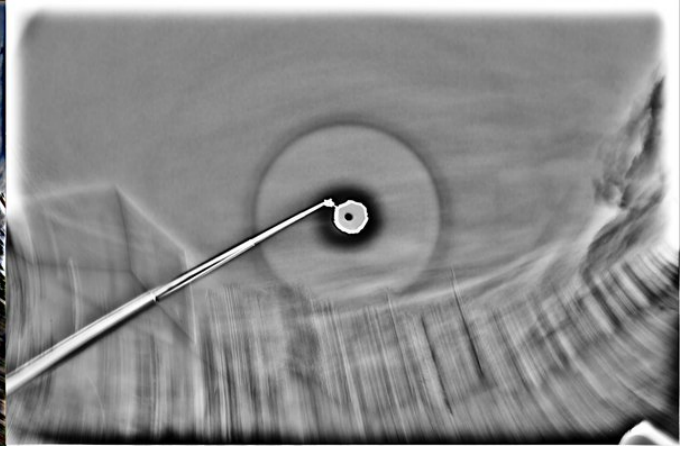

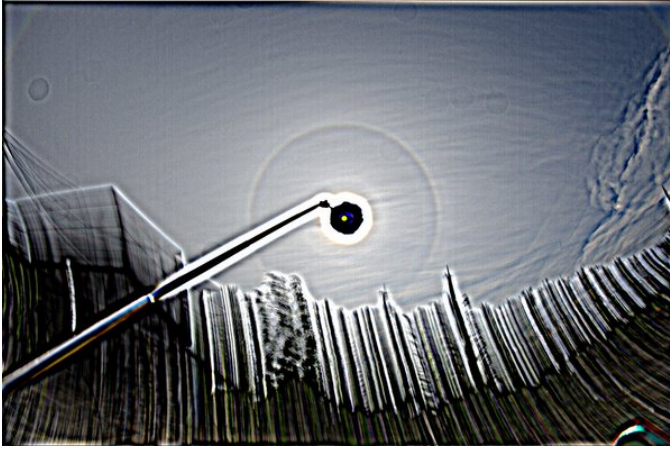

21/27 - 2025-07-06 13:35 UTC

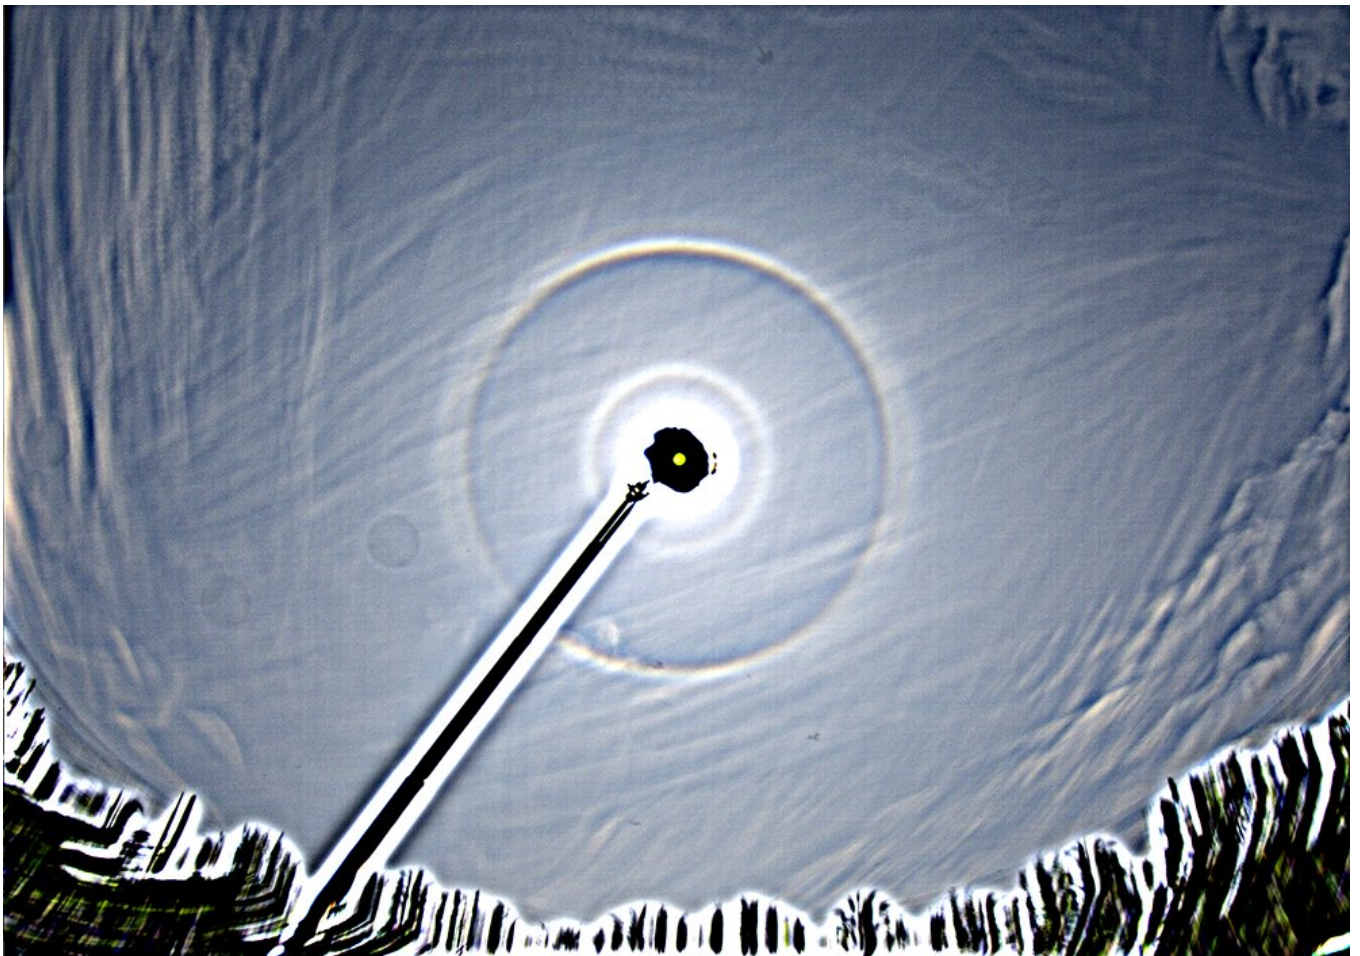

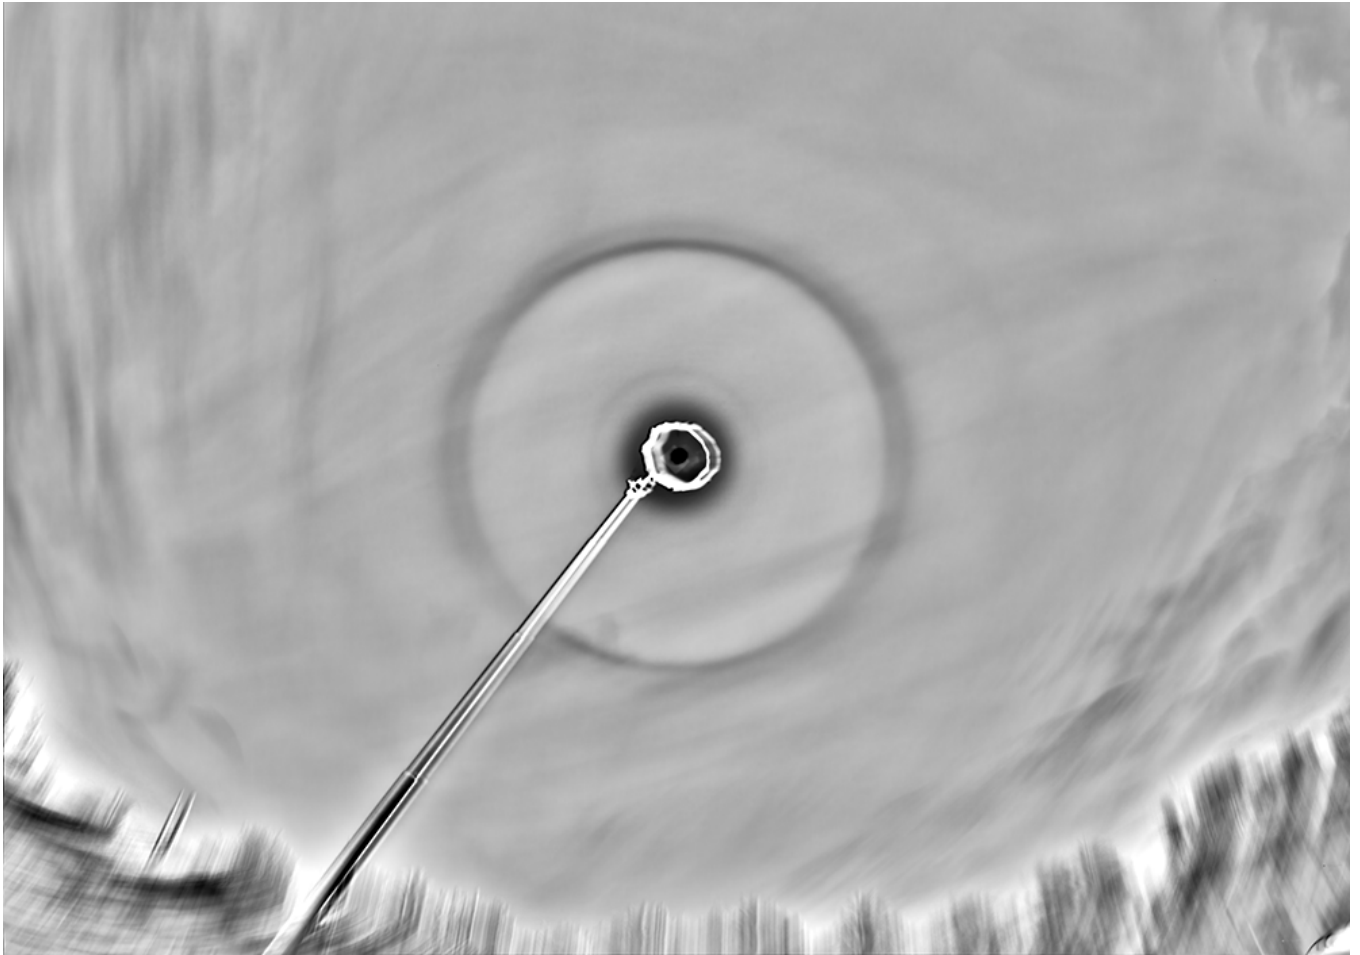

24 May. 9, 18, 22, 46°. In the afternoon. First three images are successive 200f stacks. Fourth one has all of them.

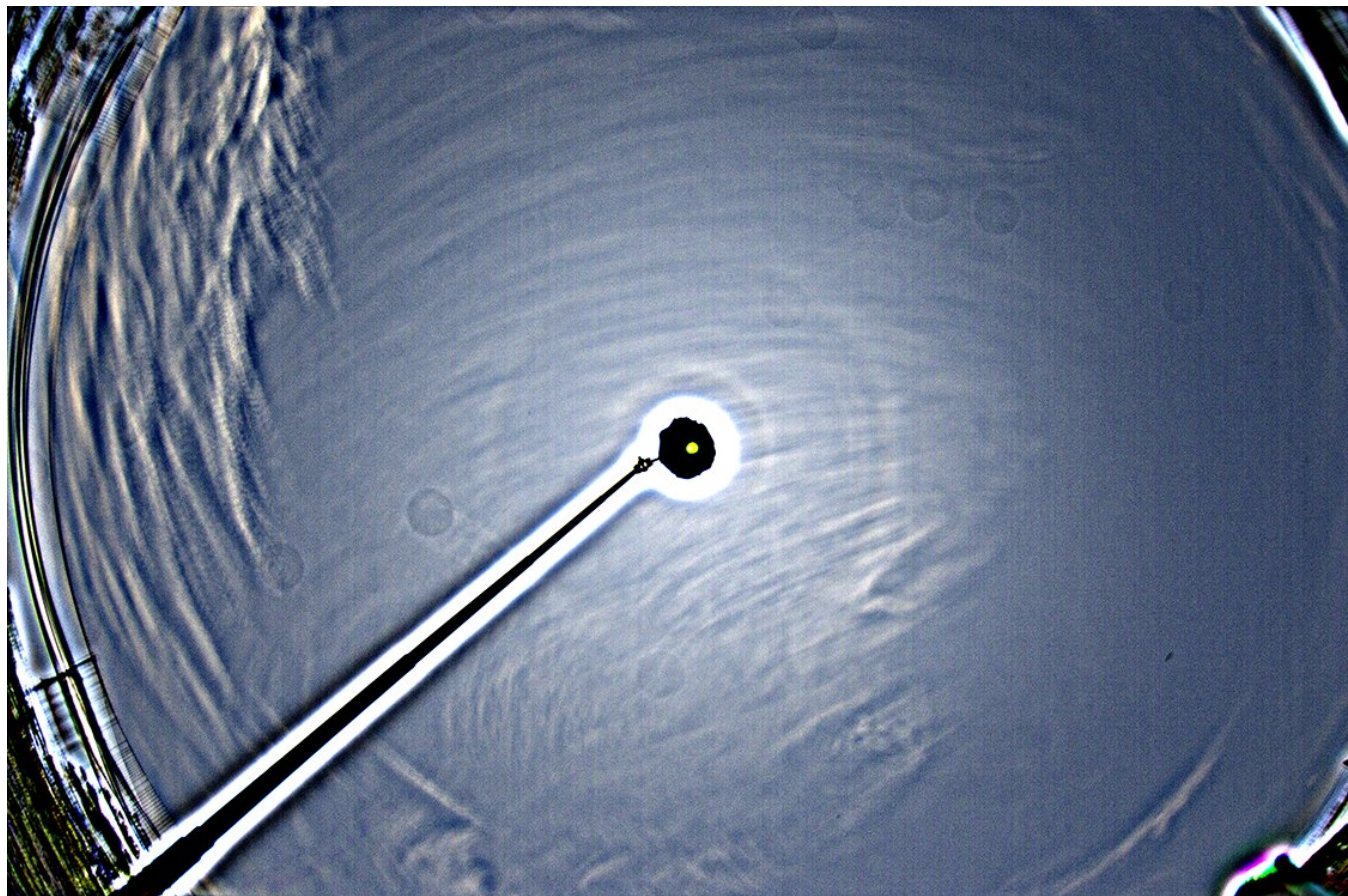

22/27 - 2025-07-06 13:47 UTC

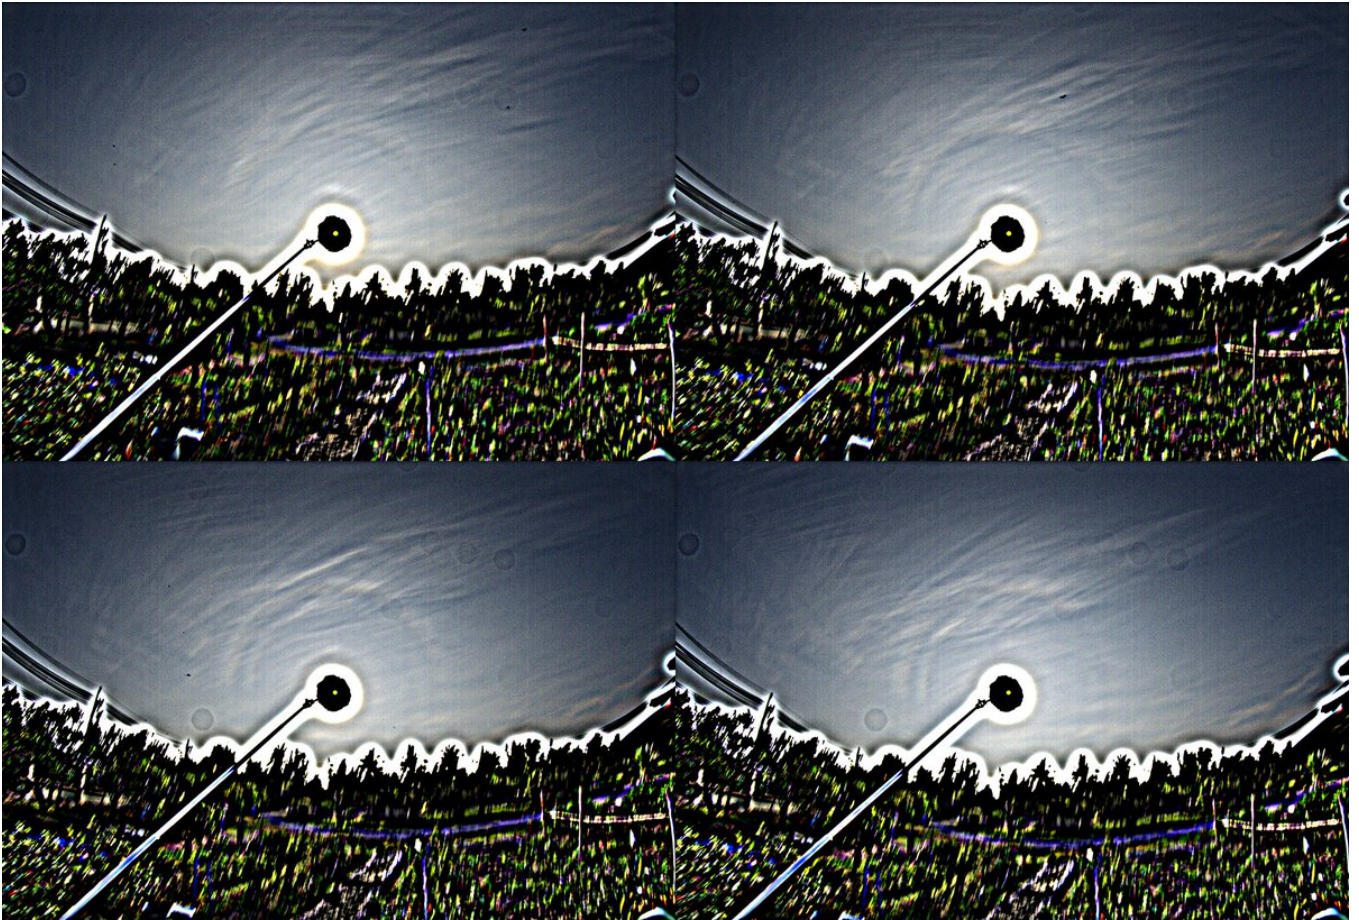

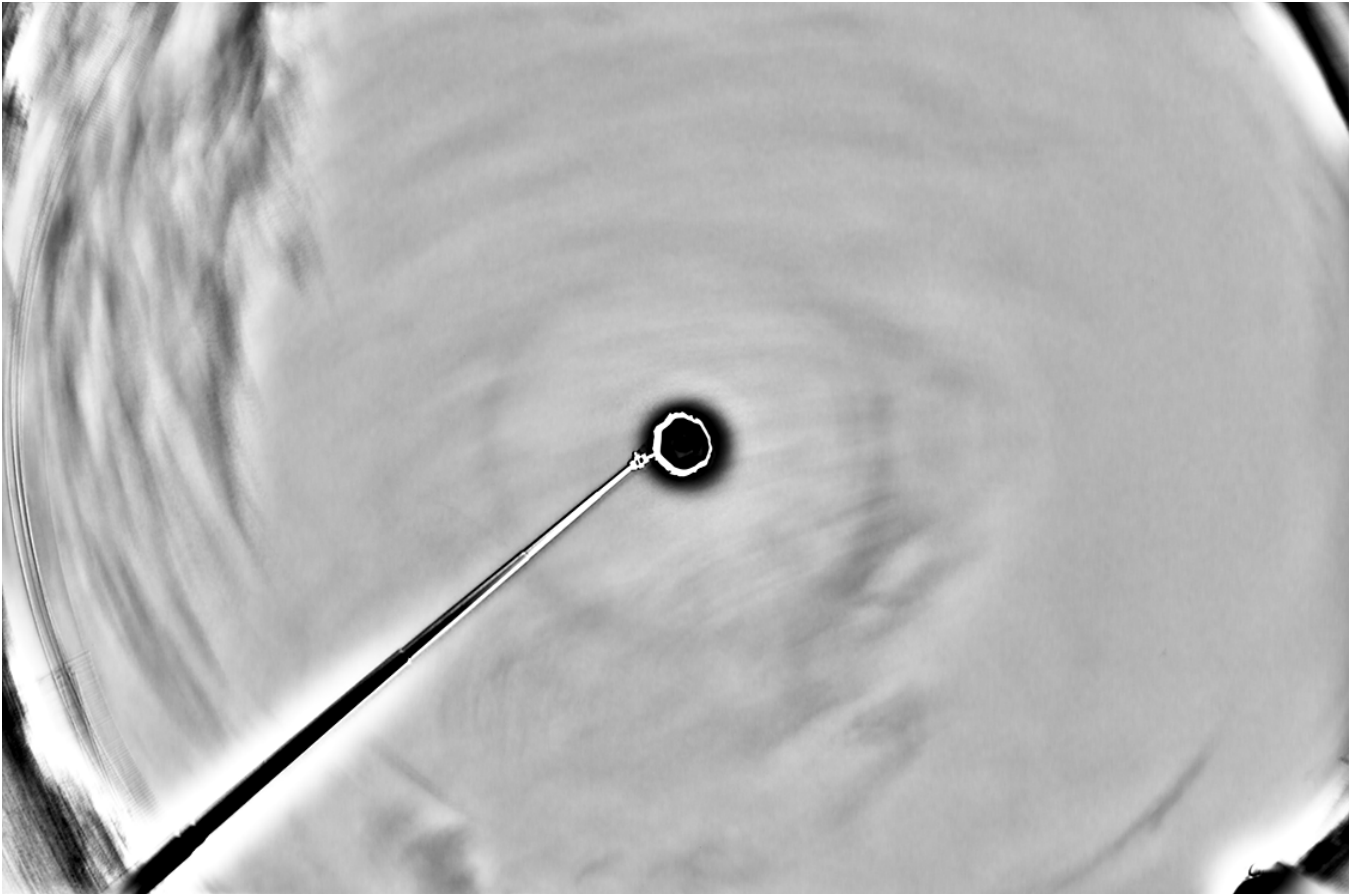

25 May. 9, 20, 22, 24, 35 and maybe 46°. Two versions of f260 10s stack at 1007-1051.

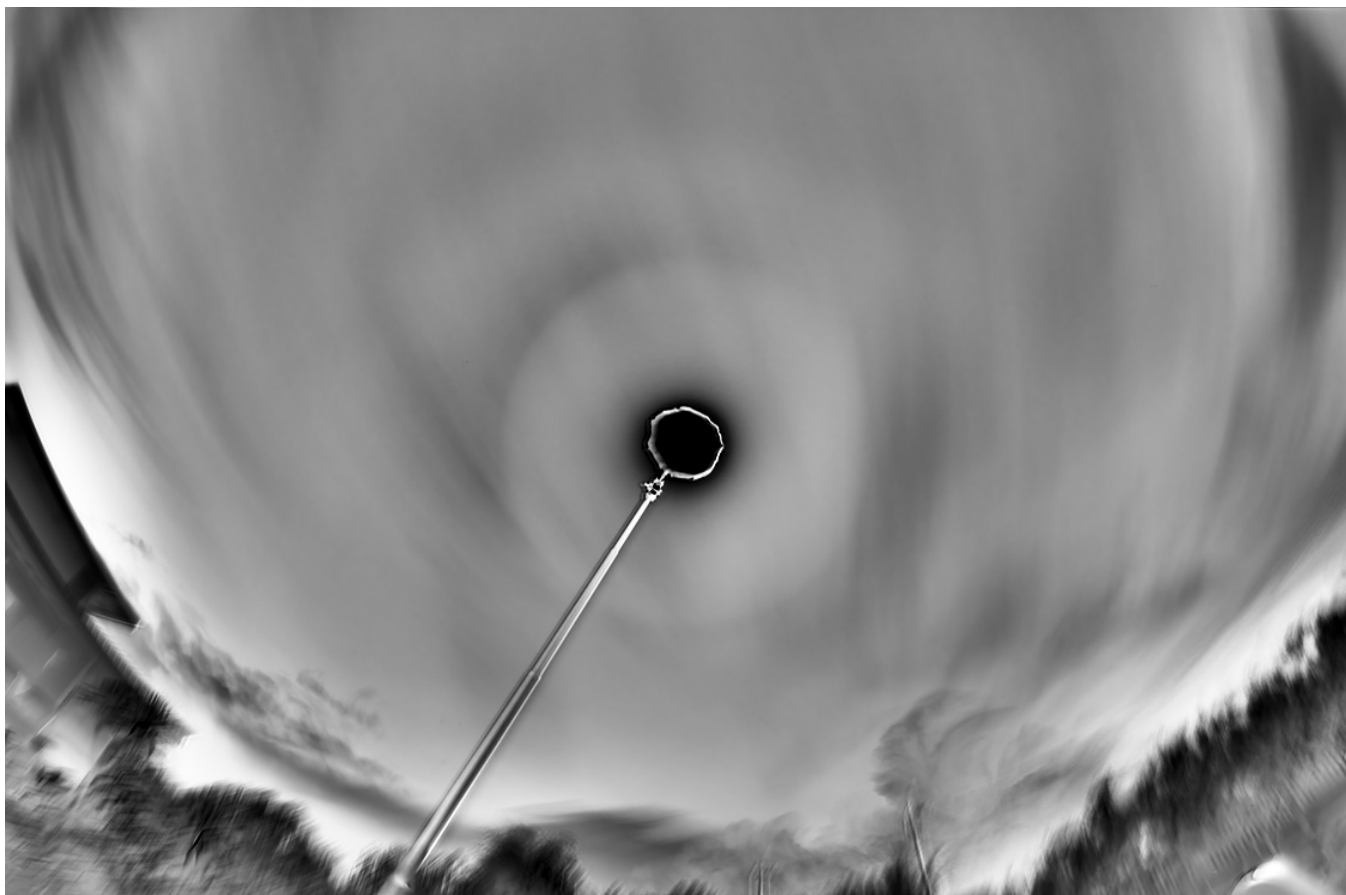

23/27 - 2025-07-06 14:05 UTC

26 May. 1) 54f 10s stacks from 0724 to 0800 – 9 and 18° plate arcs 2-3) 1159 1216 f100 10s – sharp 20 and 18° segments on the right. Column orientation? (have not looked at simulations). 4) 1159-1216 f100 10s 24 and 35°

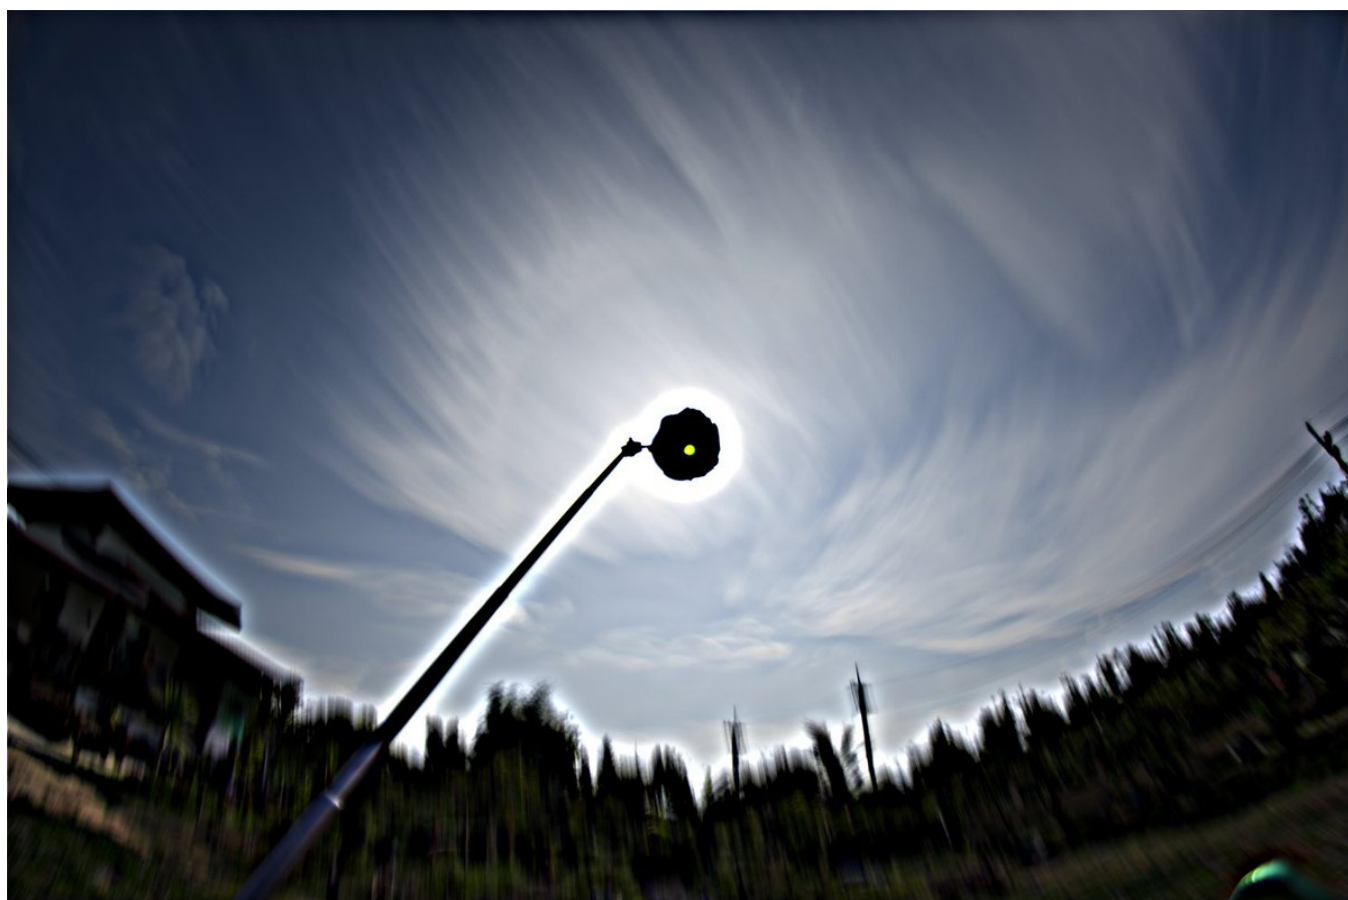

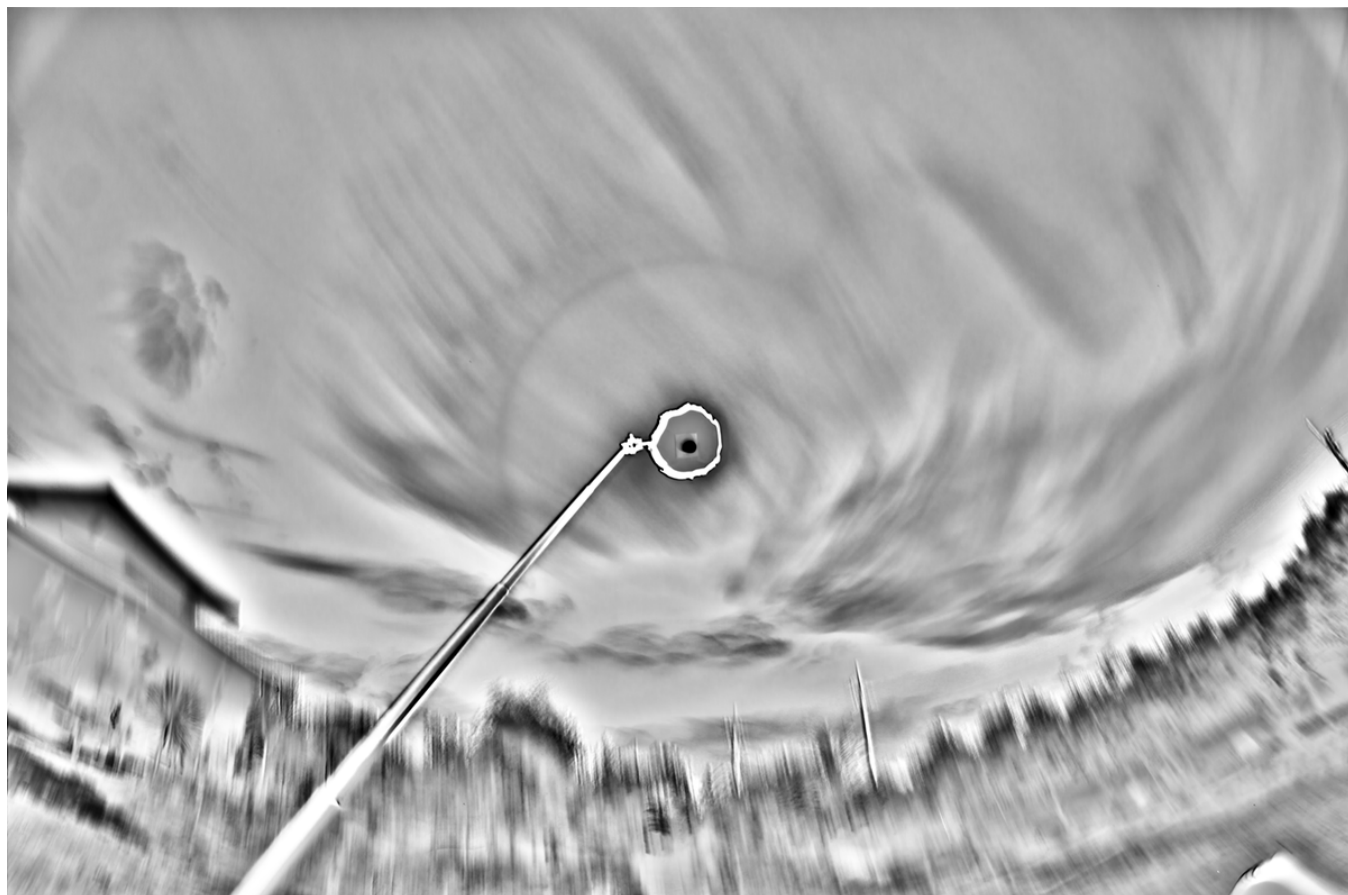

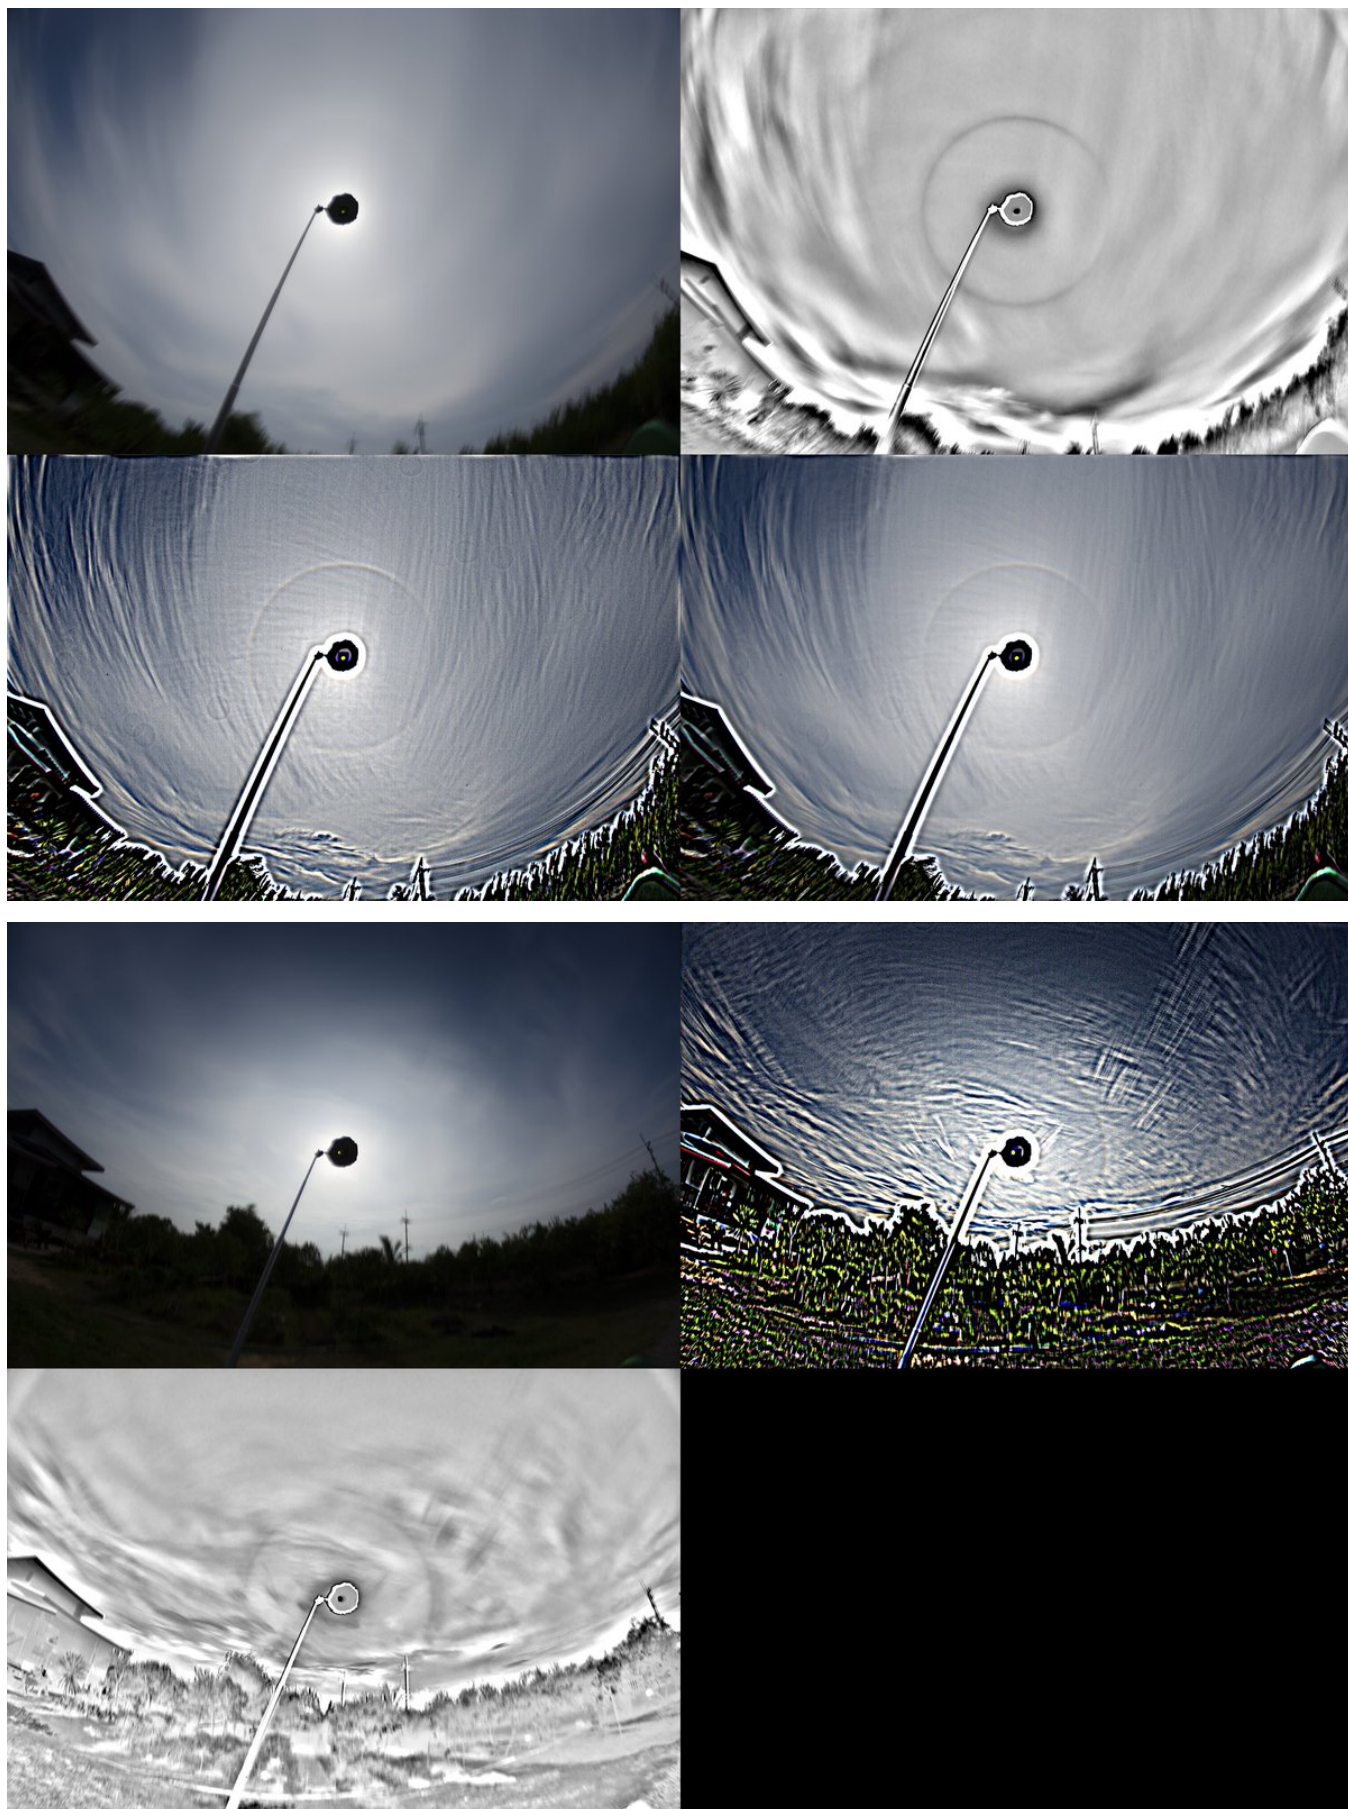

27 May. Weak 22° halo from morning to afternoon.

28 May. Only 22° halo on this day. 100f 10s.

29 May. I have named this folder as having 9 and 24°, but I am not so convinced now. Maybe there is no odd radii here. 34 and 77 frame stacks 10s interval.

27/27 - 2025-07-06 14:48 UTC

30 May. Weak 23° plate arc in the morning. 87f 10s. So that's it folks. There was an odd radius display on the day of my departure 31 May, I photographed right until the moment my landlord came to take me to the airport. But that folder of photos has mysteriously disappeared.
