19/20 Feb 2026, Rovaniemi. I have been wanting to have a "Sievi type" display this winter: <https://t.co/YNowxWRSnN> Now it came and it's good the lamp elevation differs from the usual near-horizon.

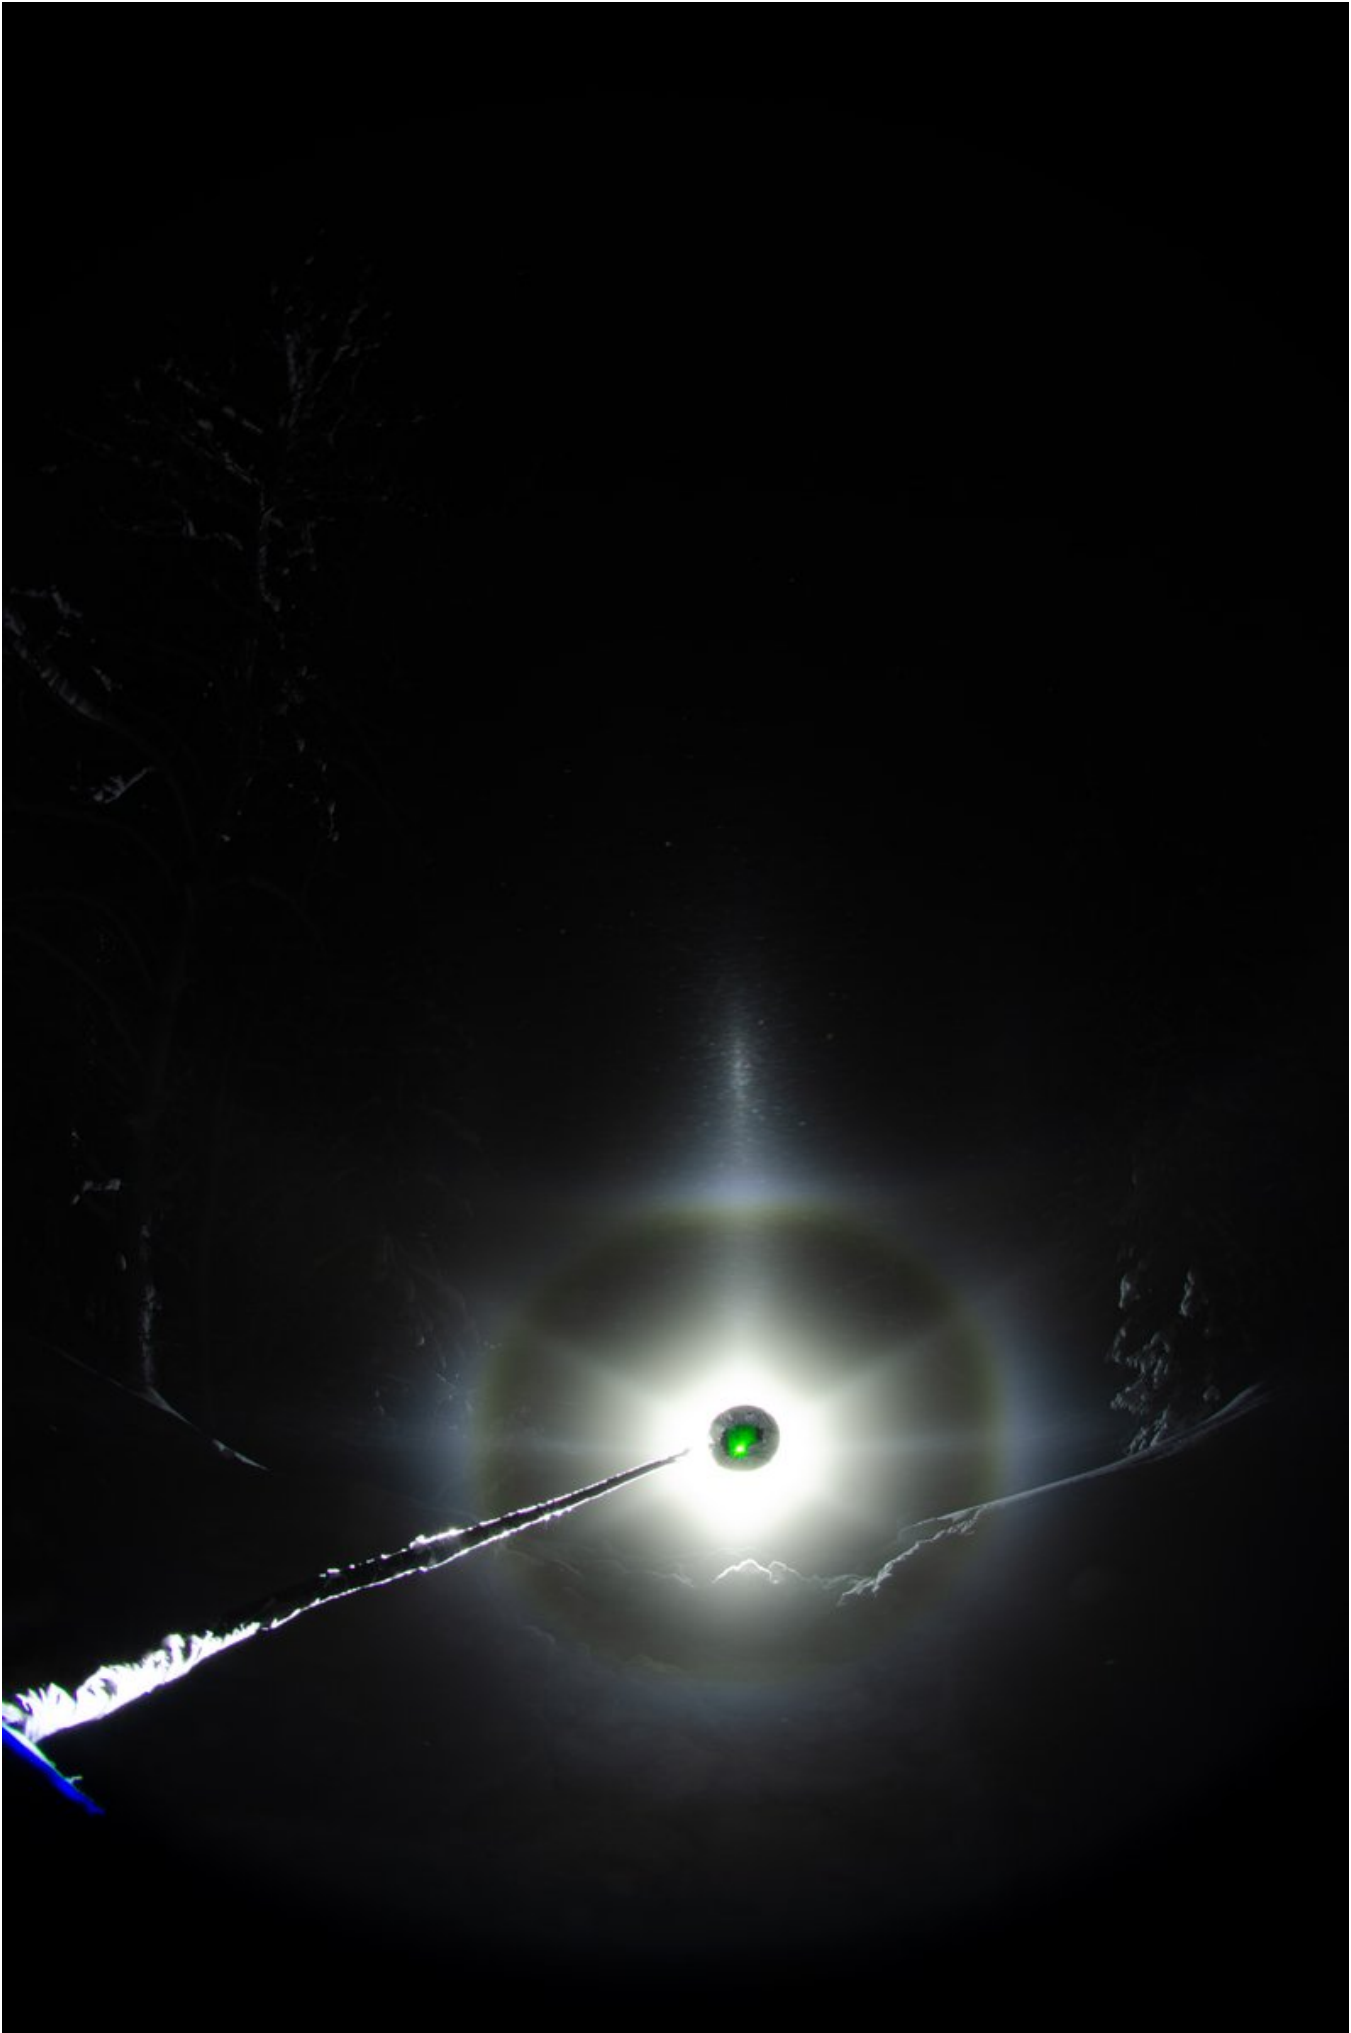

There is no Parry arc or tangent arc. It would seem like this is due to Parry-Lowitz orientation in thin plates, but the simulations I have managed leave much to hope for.

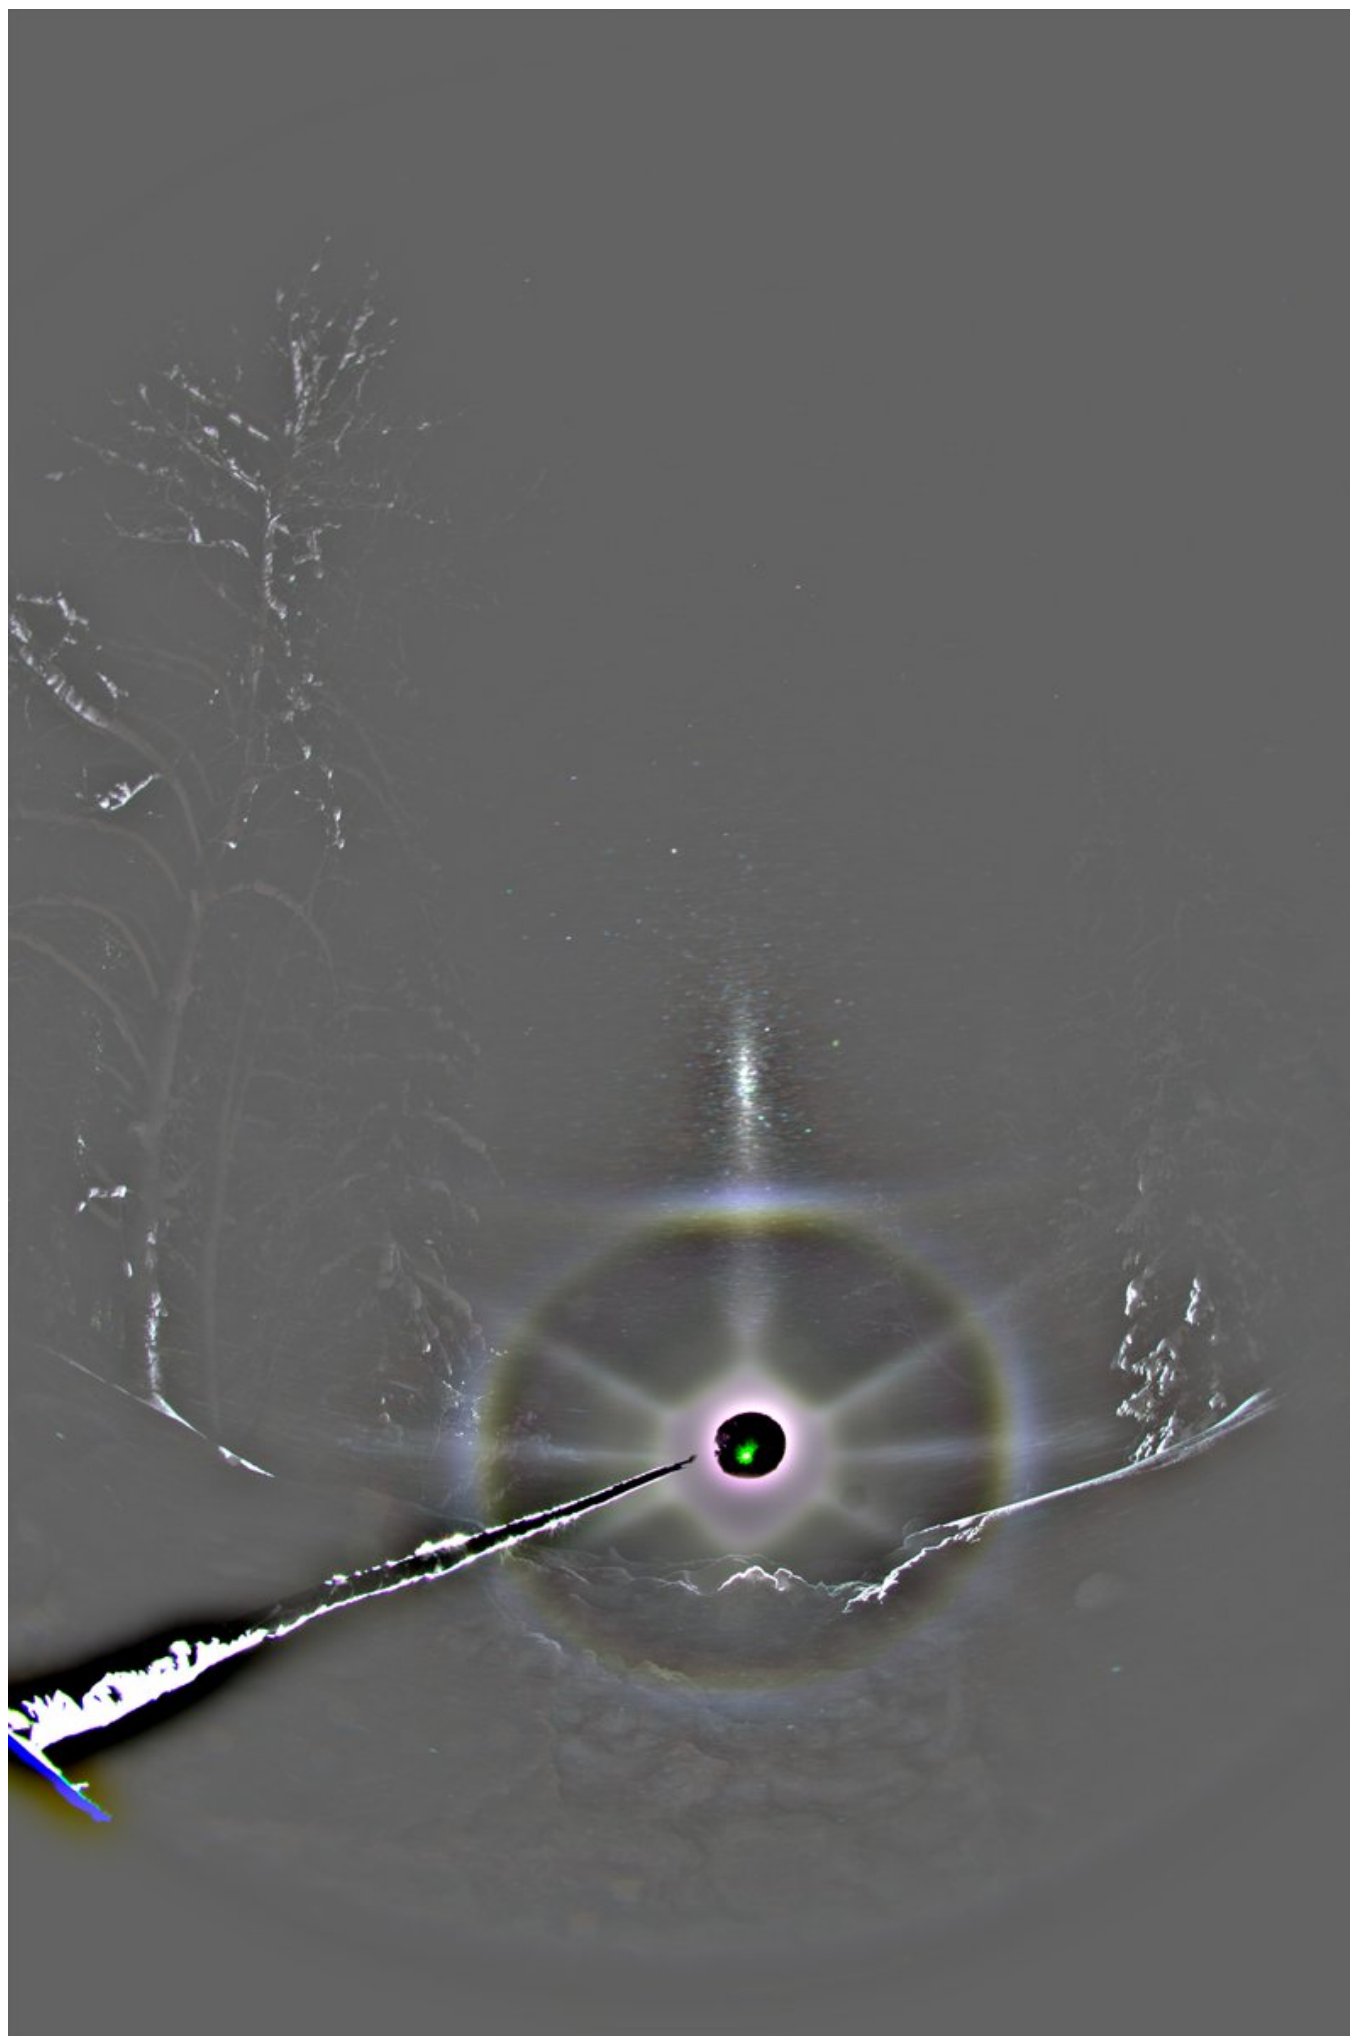

I think I have also a crystal sample involving this stage but I don't expect much of it. I was looking forward to photograph halos the whole night, but the fun was cut short by the snowgun stopping at around 2225. I was in a nearby field and could hear its sound change and then just silence. I stayed around and later a guy came who said aggregate had malfunctioned. Won't be happening anything for a couple of days.

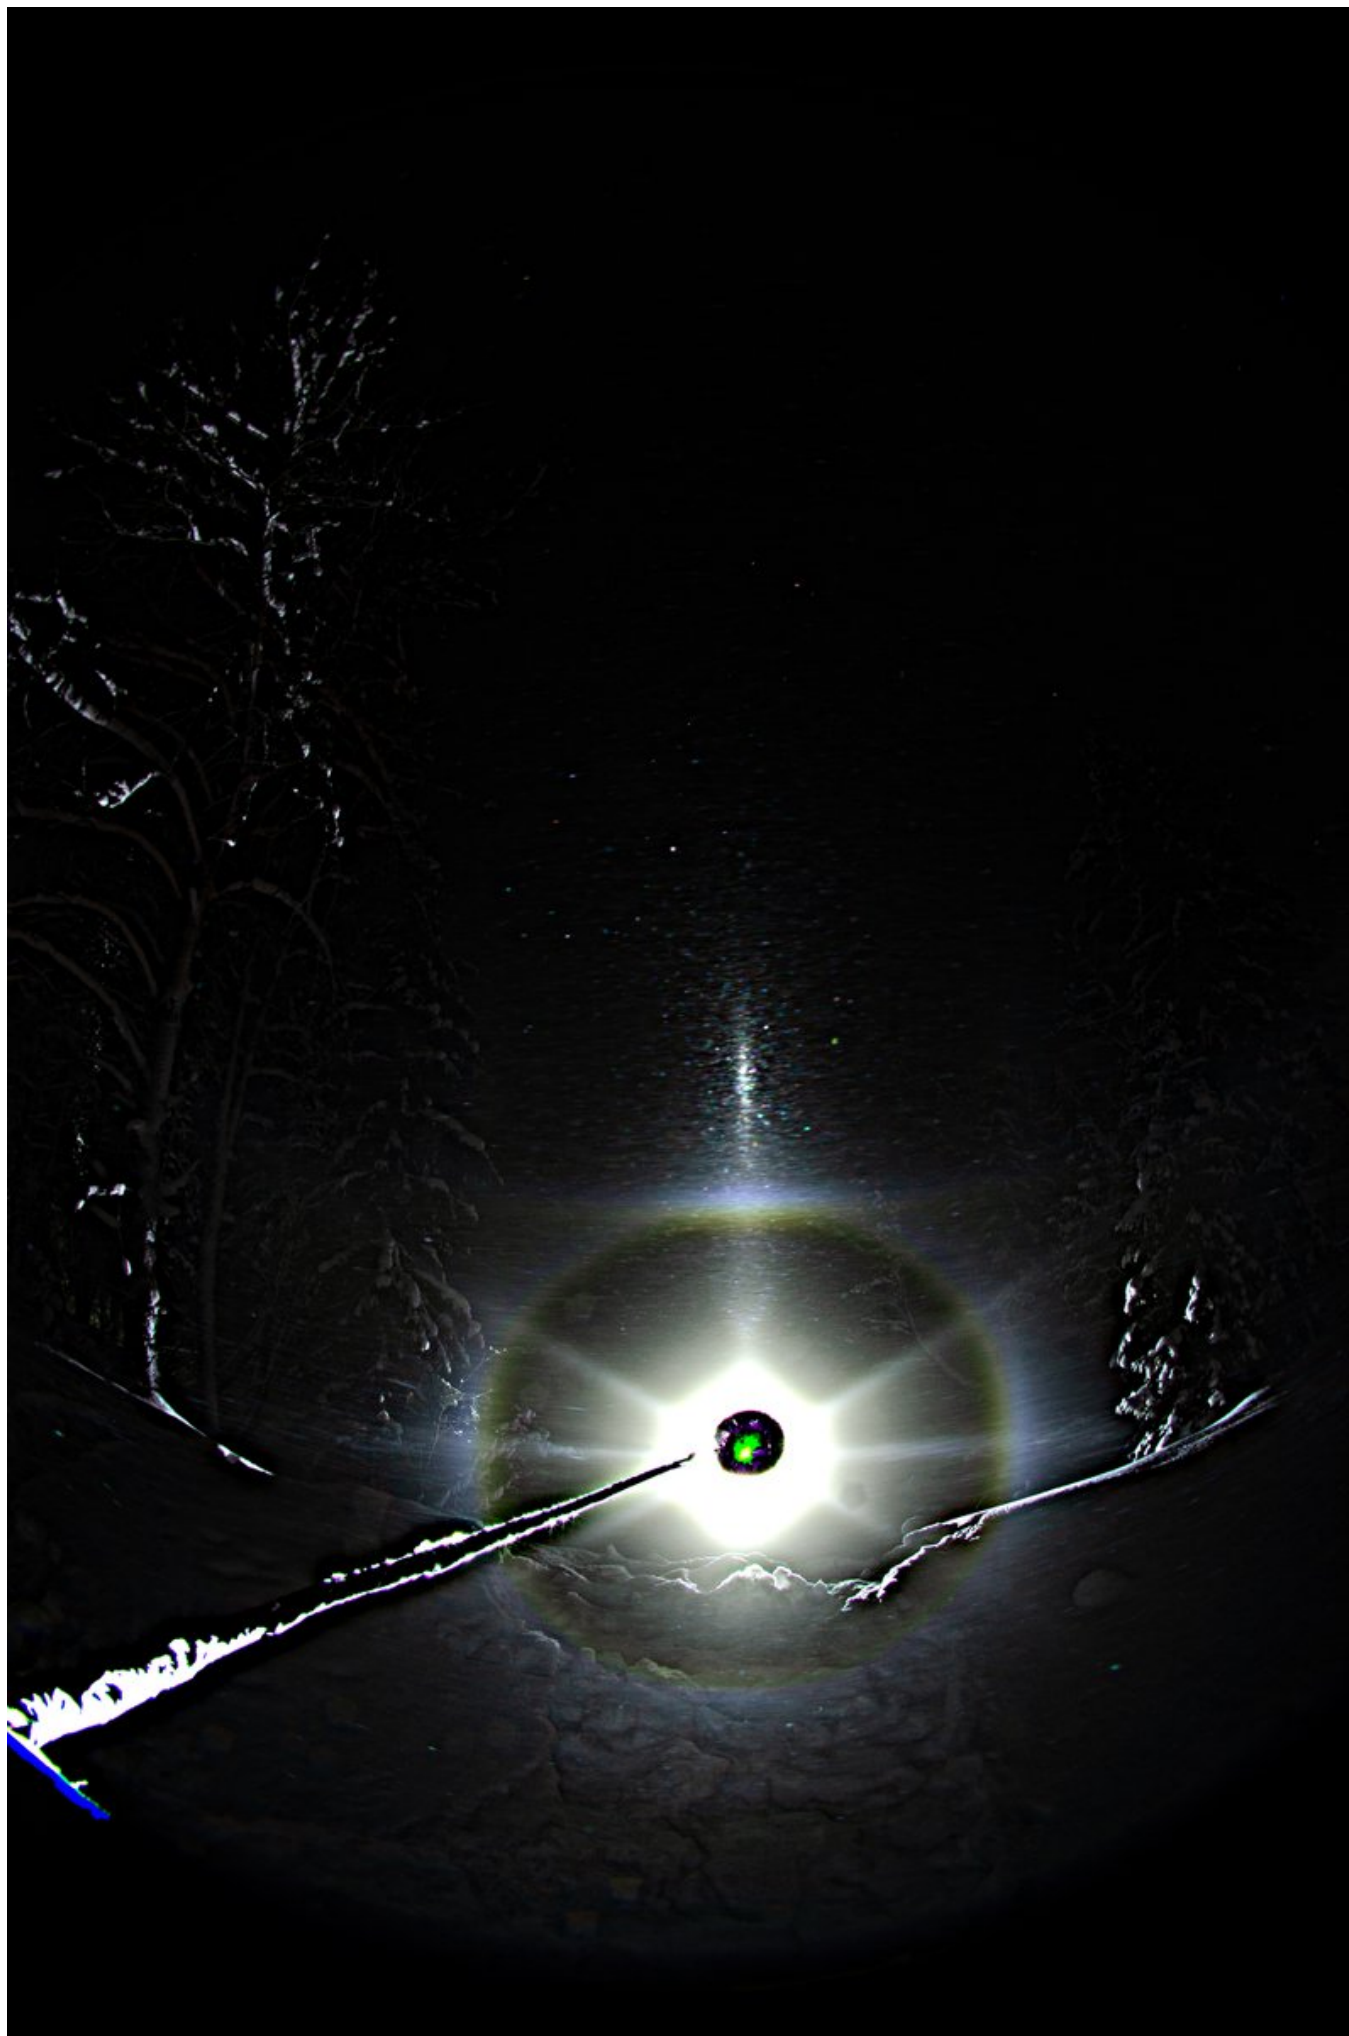

Too bad I didn't check the time when the machine stopped. It's would be nice to know how long diamond dust lingers after the source is cut off. Now I have only an estimate. I checked the time at 2234 and estimated the gun had stopped 10 minutes earlier. The last of the pillar in the flood of the gunning site building light disappeared at 2300. So the diamond dust was around for 35 minutes after the machine stopped. Don't know of course if somewhere else it was still present. The weather was quite calm.

-25 C in car thermometer.

19/20 Feb 2026, Rovaniemi. It dwindled at the field I was, so I visited the gunning site. There 9° halo struck out in the beam. Not clear big crystal 9° halo like two nights earlier, and when I got the photography going, it weakened. Anyway, it would seem to be present in the 16 x 30s stack here, as well as possibly some 18° action on the sides. This was the last photos I took, some time later the gun stopped.

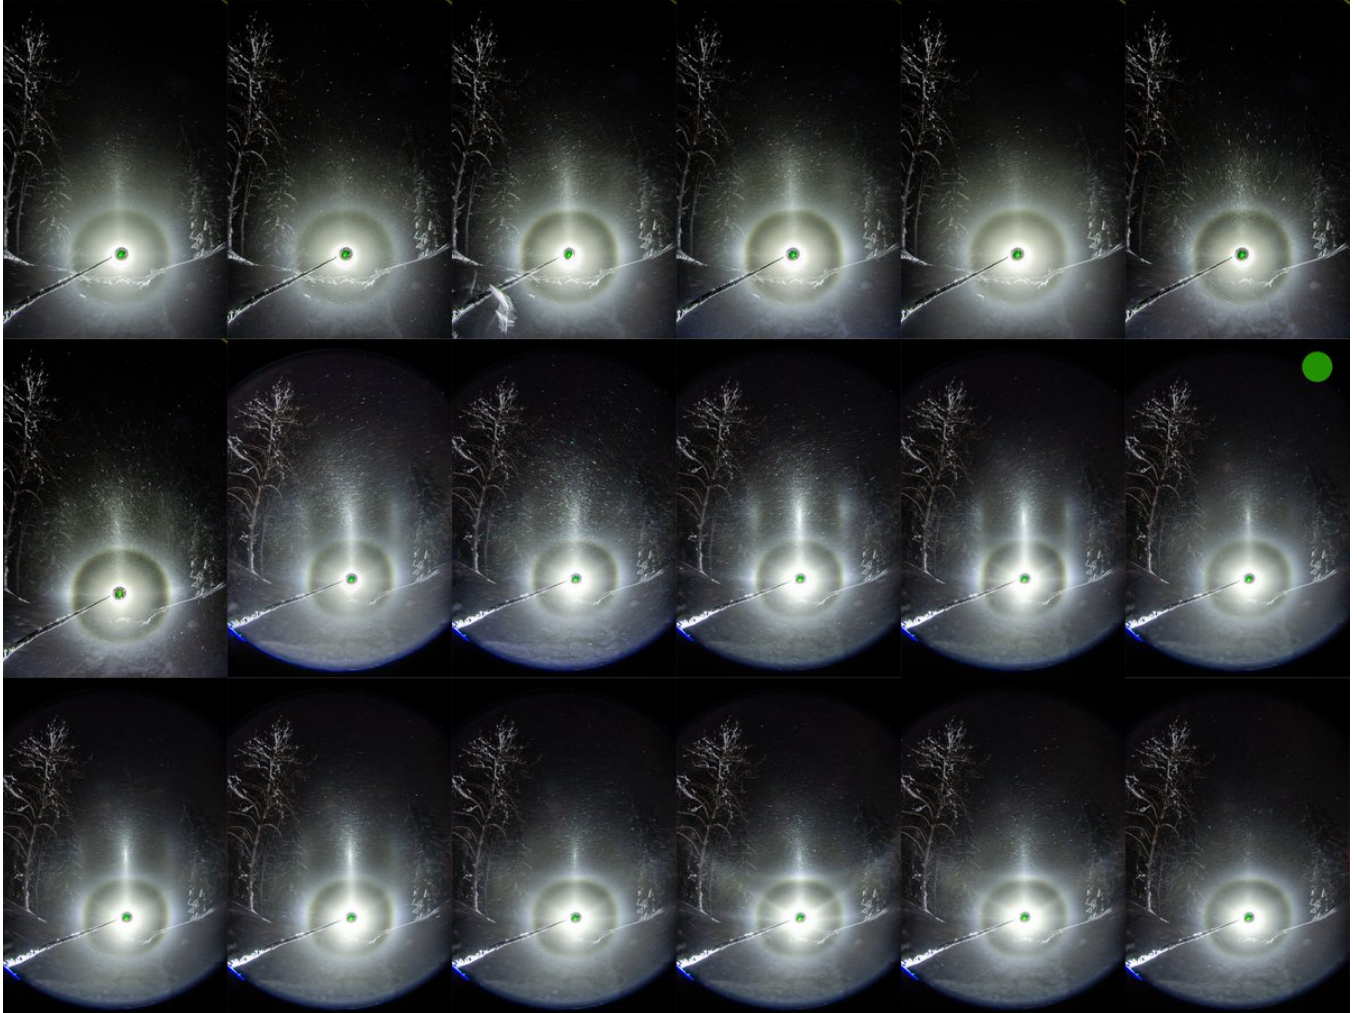

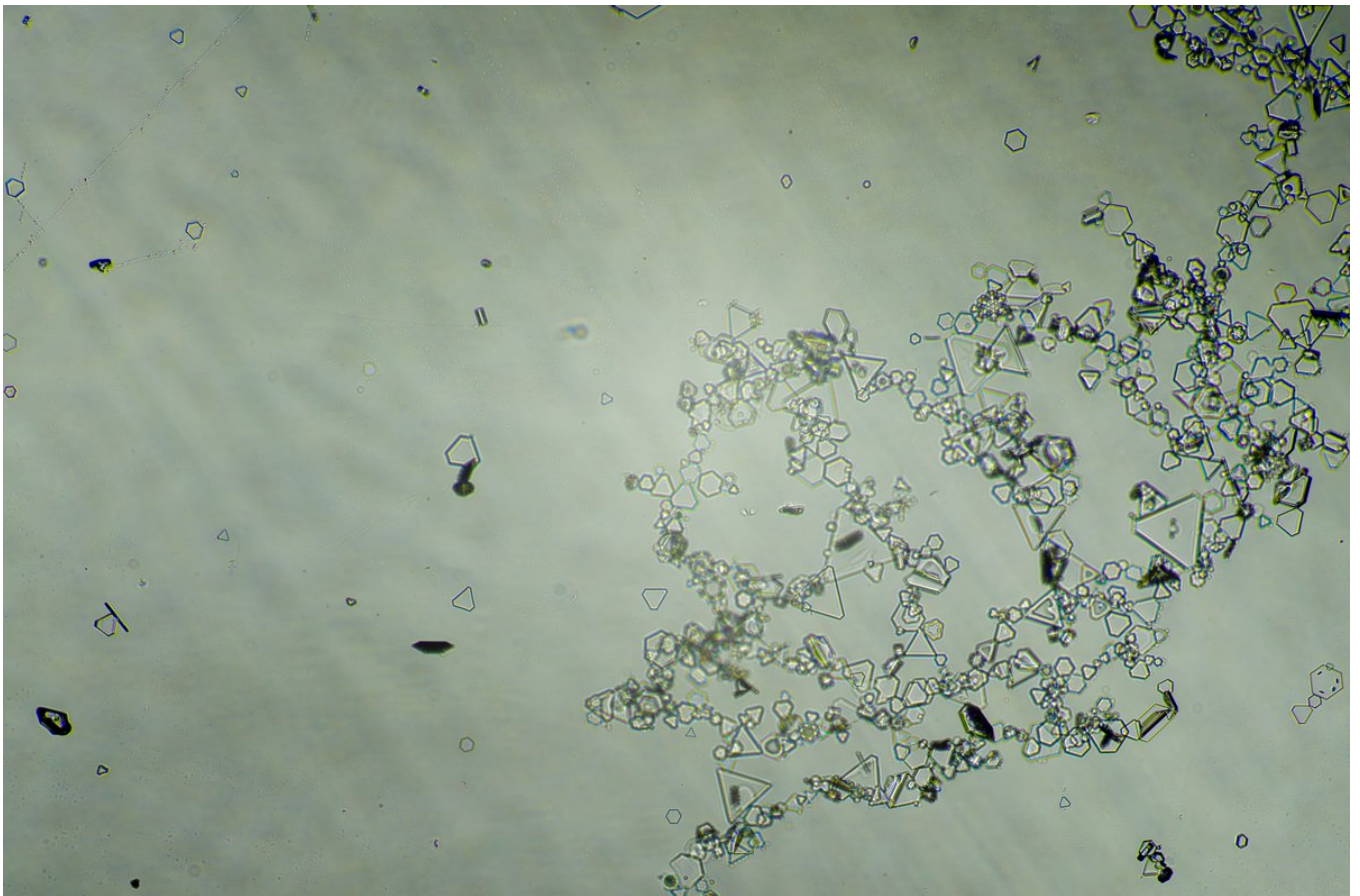

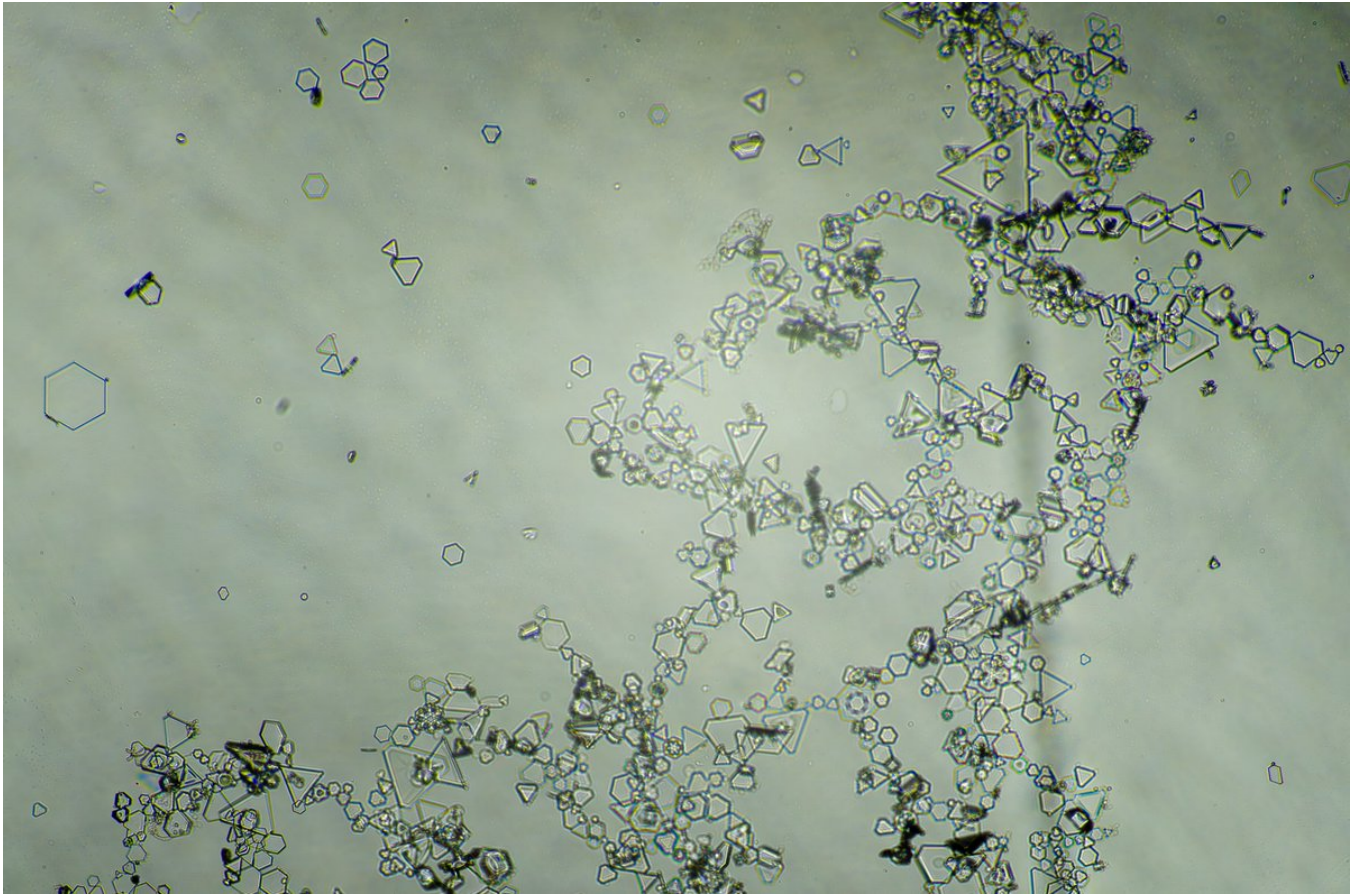

3/7 - 2026-04-20 15:17 UTC

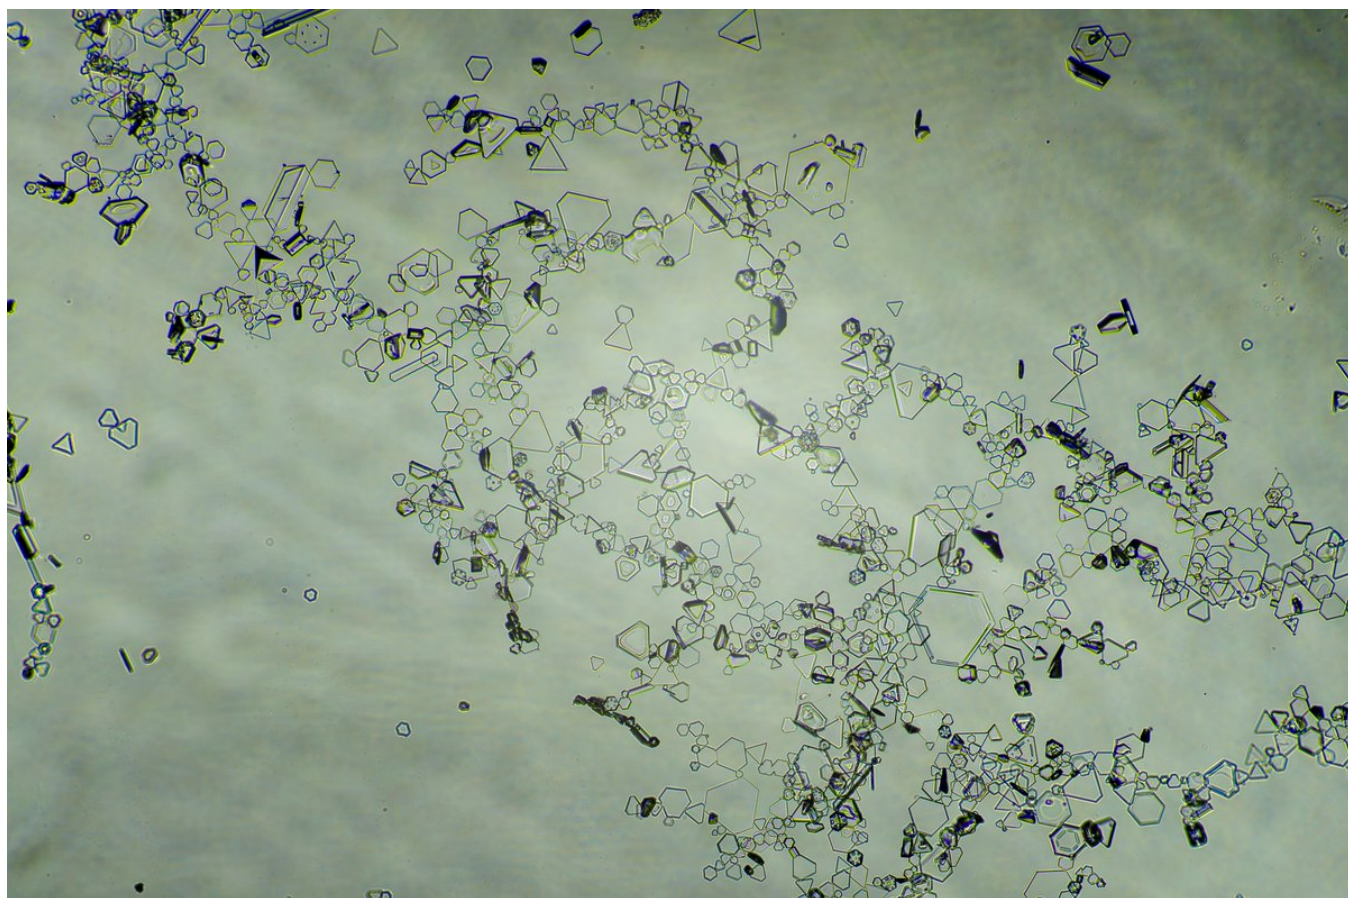

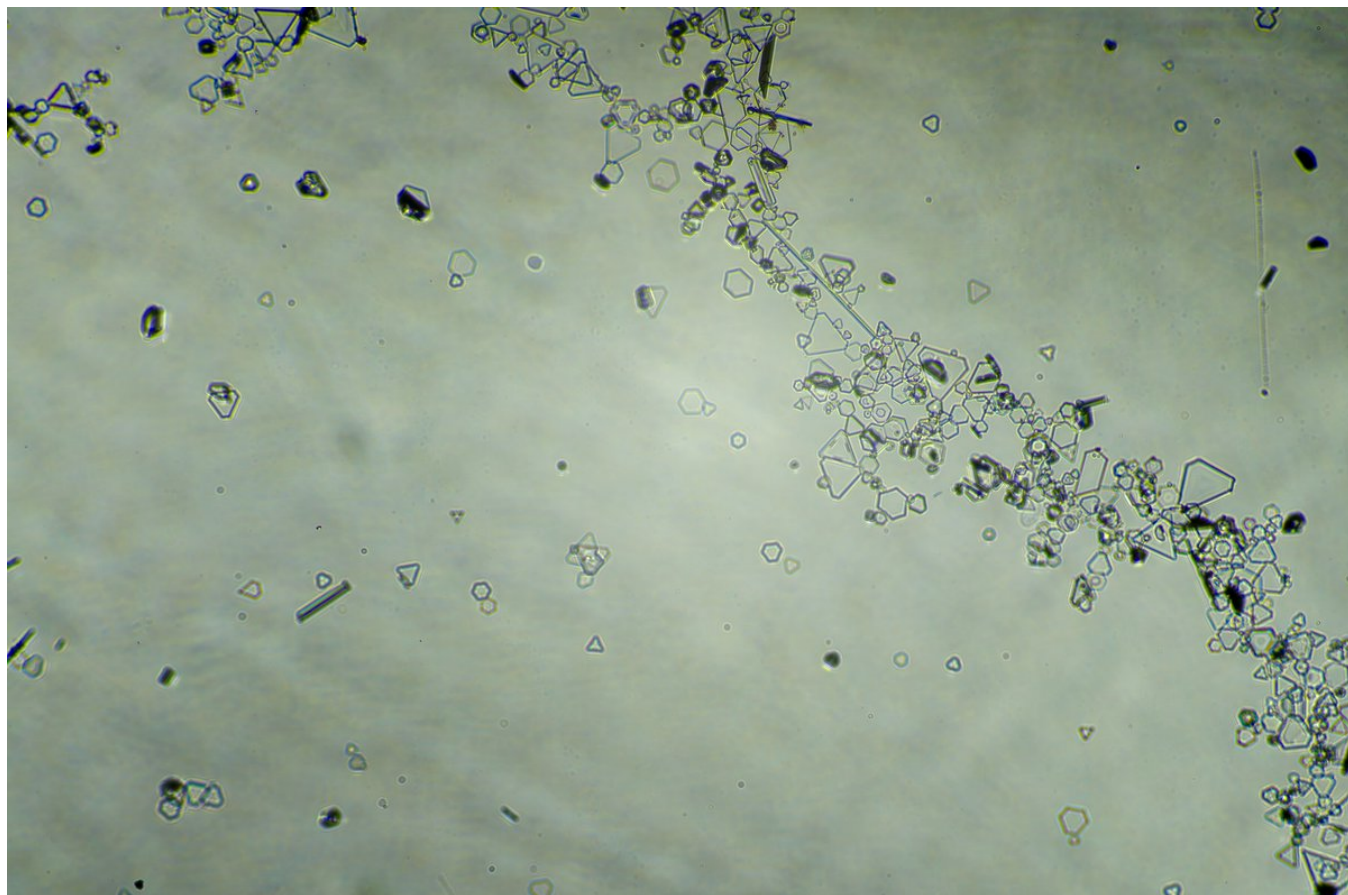

19/20 Feb 2026, Rovaniemi. I took two crystal samples. The photos in this collage correspond to the time of the 2nd sampling, half and hour long, including the crystal photography itself, which started after the photo marked with green dot. In the collage is every third photo from the sampling time, 5 minutes break in between the camera swap. The third photo from right in the last row corresponds to the stage (3x30s) highlighted in the first post of this thread.

4/7 - 2026-04-20 15:28 UTC

19/20 Feb 2026, Rovaniemi. 2nd crystal sample photos. Unfortunately the focus was off in most images, I had not yet discovered that you could magnify the live view. Anyway, as to the mysterious features of this display – the helic arc, the top brightening on 22° halo, and the "Hastings" – I don't find answers in these crystals. But the answer must be there for those who know how to look.

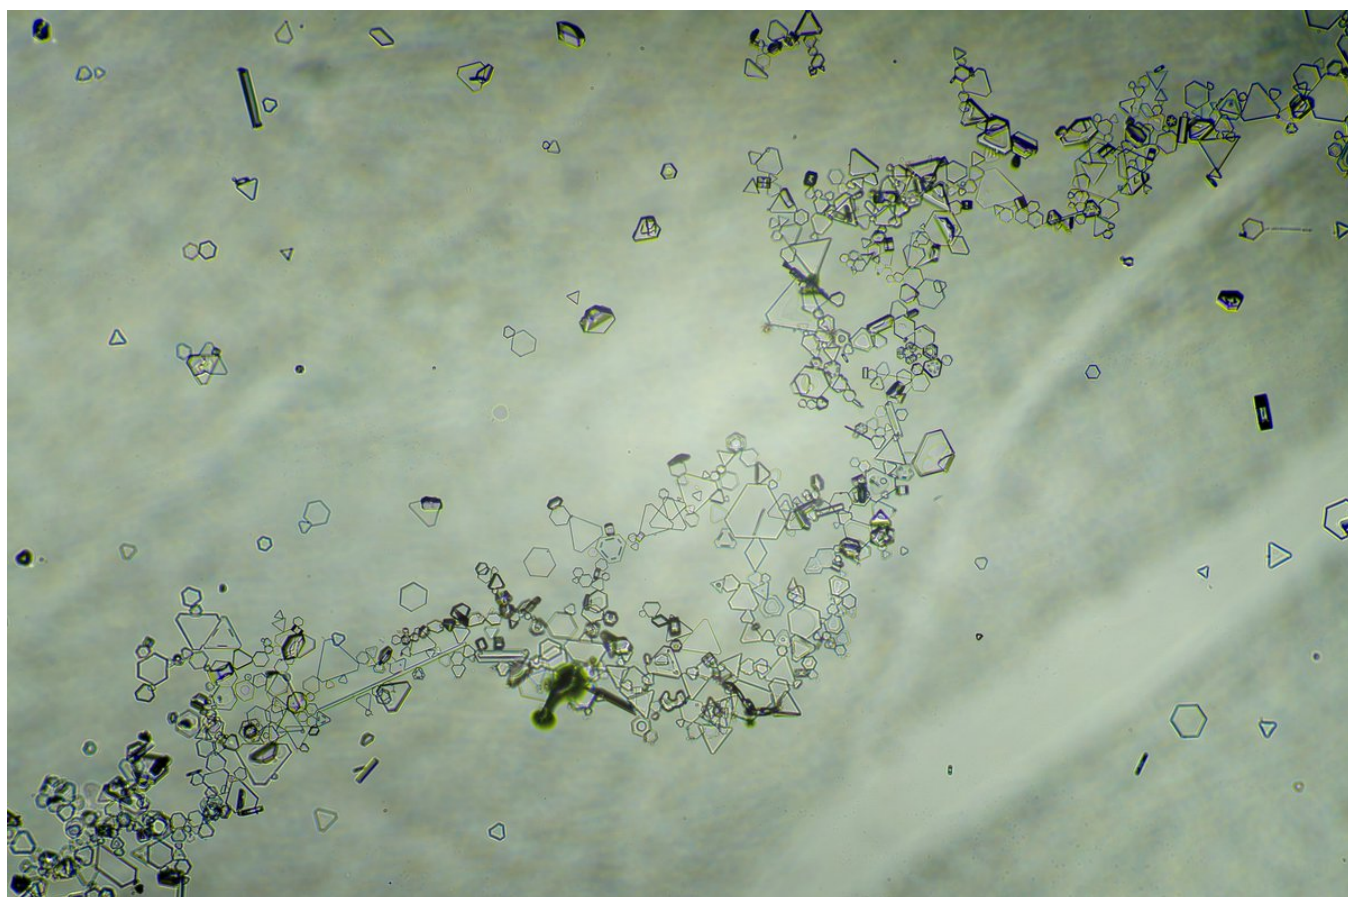

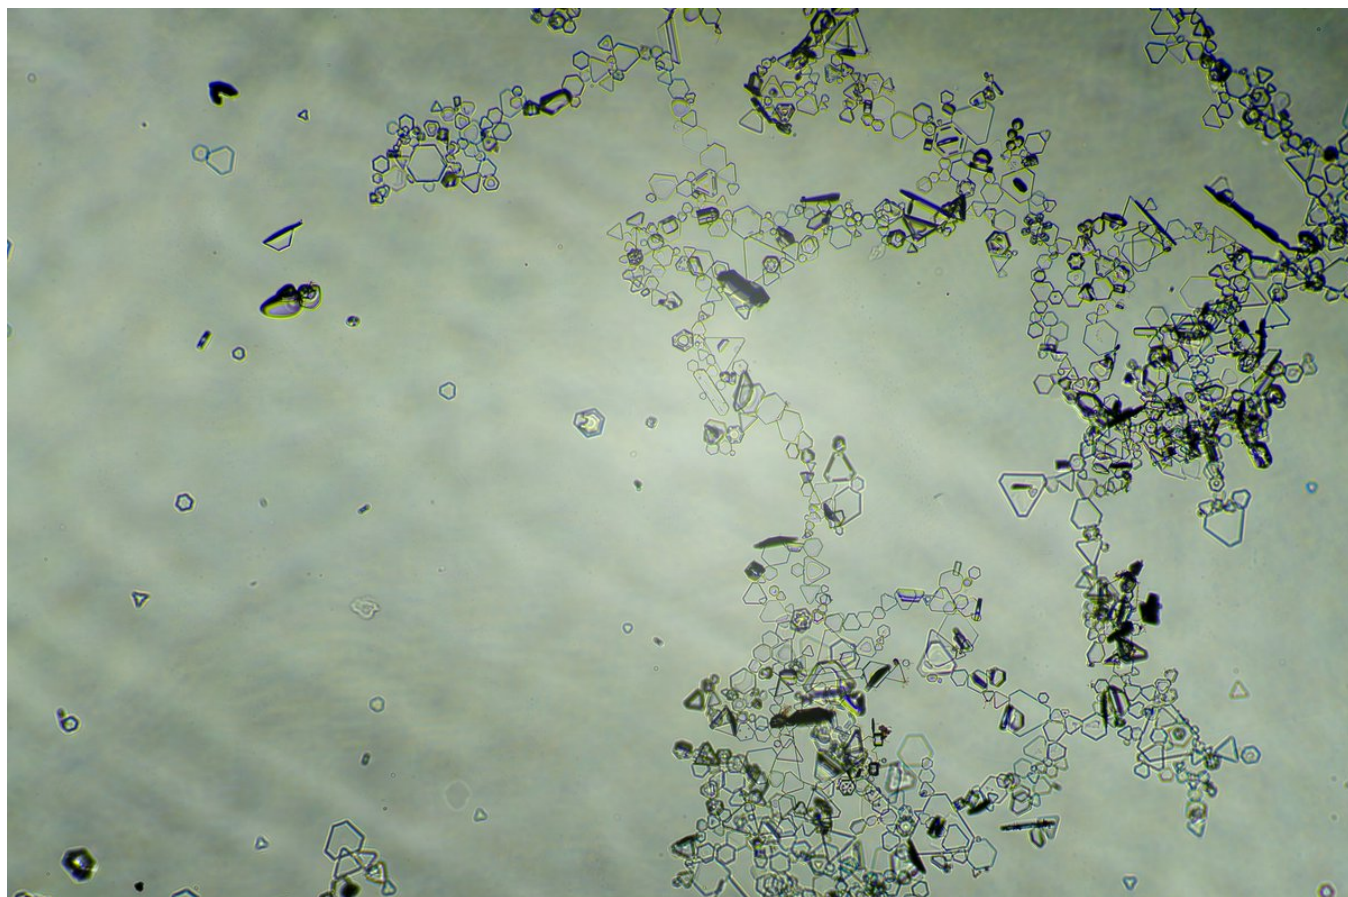

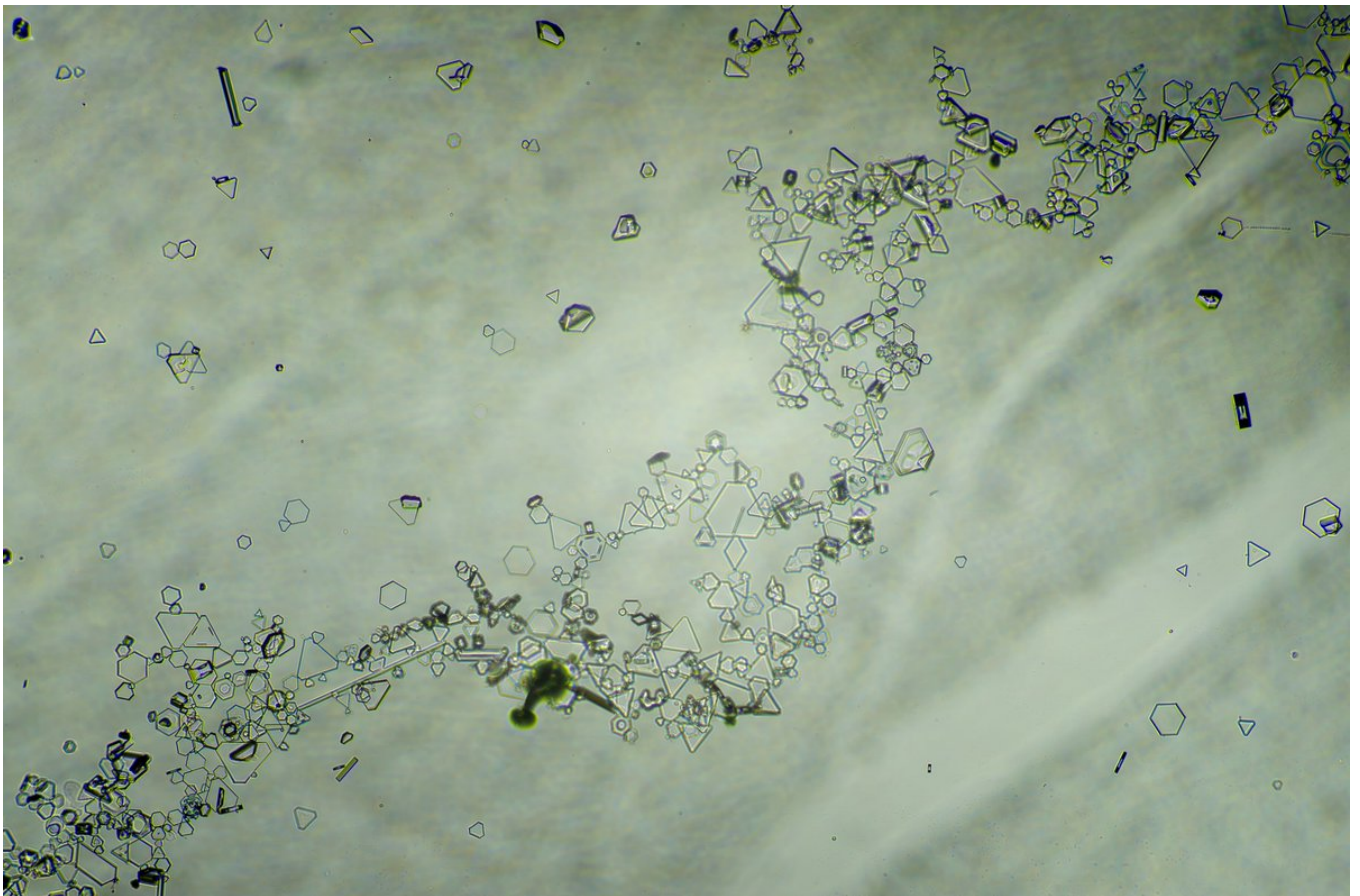

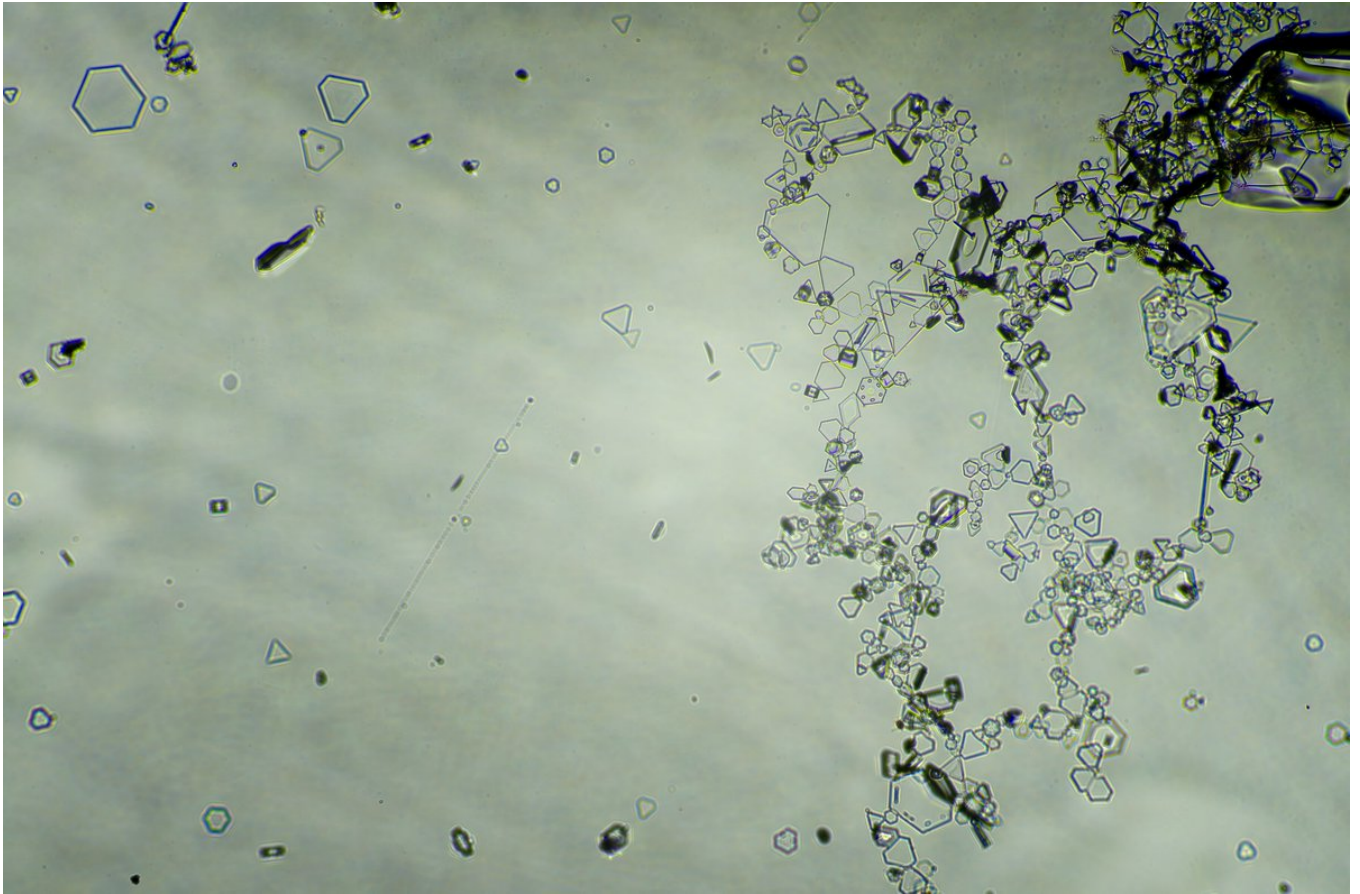

5/7 - 2026-04-20 15:32 UTC

19/20 Feb 2026, Rovaniemi. More crystals from the 2nd sampling. There is really long needle in the

third photo. Likely trapezius, possibly Moilanen type. Actually, these crystals seem to be same as in one of the above post's photos, just rotated.

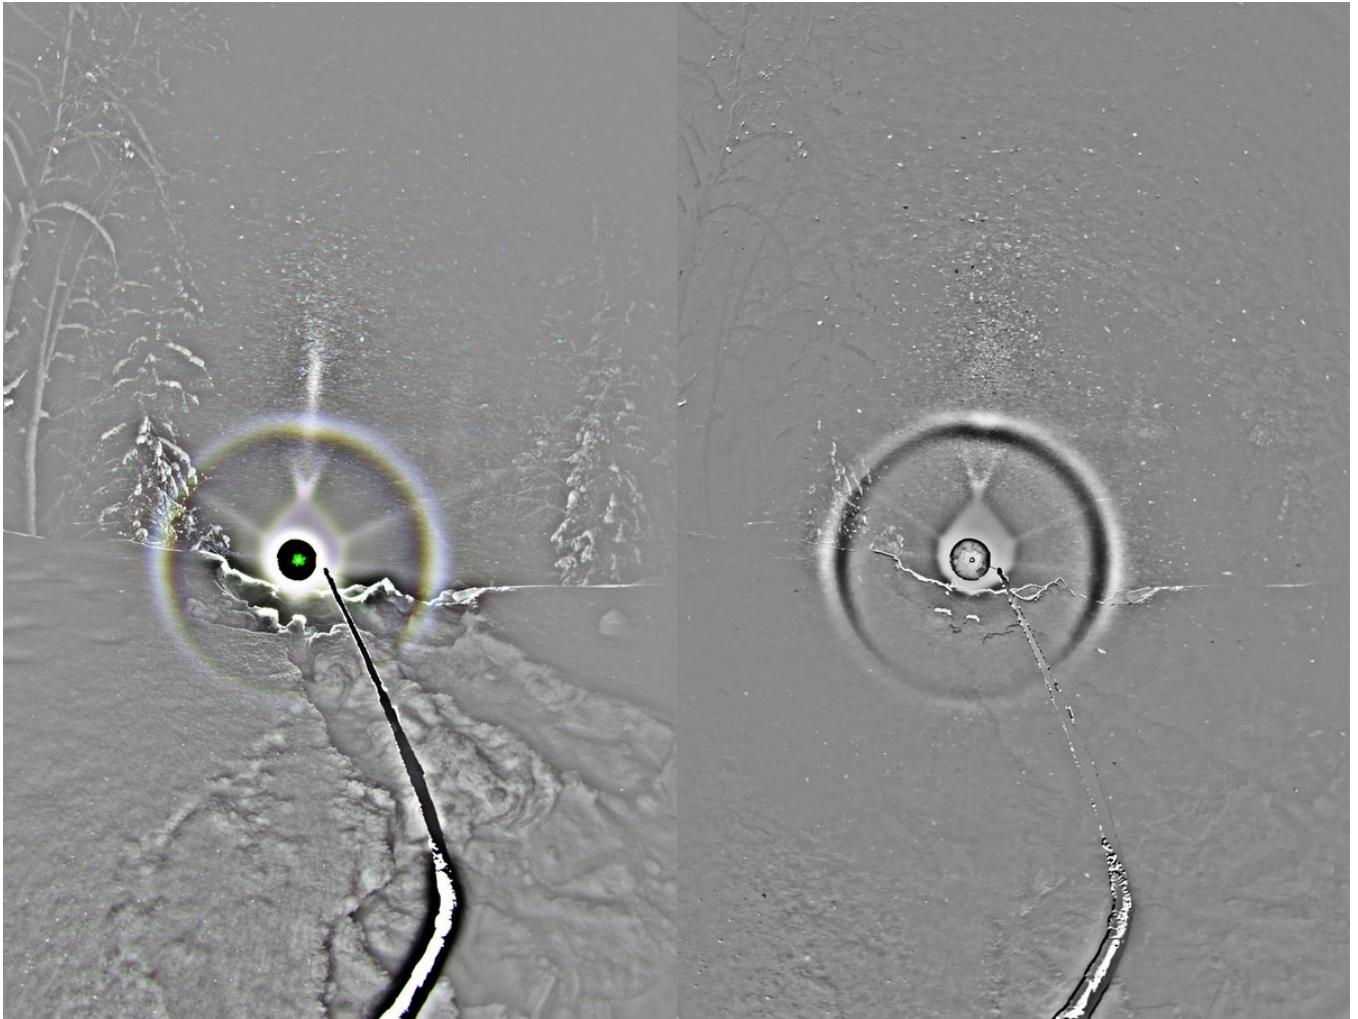

6/7 - 2026-04-21 12:27 UTC

19/20 Feb 2026, Rovaniemi. Another stack. 6 x 30s. The single images are max, ave and median.

7/7 - 2026-04-21 12:45 UTC

19/20 Feb 2026, Rovaniemi. Following immediately the previous stack, 22 x 30s. Is there bottom brightening on 22° halo? Supposing the top brightening was tanarc, at this light elevation the top contact point is more concentrated than the bottom contact point, but I would still expect to see enhancement at the latter point.

Probably no tanarc is present, instead the top brightening is some kind of Lowitz-Parry intermediate arc. However, whatever the crystal shape, we should expect an corresponding arc against the snow some way below 22° halo. But i see nothing there either.

bgr ave, br ave, Camera Raw ave, Camera Raw max
