In an alternative interpretation any length tail on 22° parhelion is parhelic circle. As we know, parhelic circle is contributed by the 3-hit rotated parhelia raypaths that make a segment that is wholly white because the colors overlap. And in 22° parhelion tail colors overlap in similar manner. The only difference is that parhelion has the colored head, whereas the 3-hit rotated parhelia don't – it's throughout white. Earlier, I had presented a scenario in which rhombus shaped plate oriented crystals make a parhelic circle that is dominated by the 3-hit rotated parhelia raypaths: <https://t.co/JqUI8MWRNF>
