It's got the same two colors we see in the psychedelic glitter! That palette comes from around 4th order thin film interference, so the thickness of plates is around 2 um. <https://t.co/Cd5mvpTBH6>

There is one mysterious case I have photographed that has more diversity of colors. <https://t.co/gzDgFApla0>

Thinner crystals could be the culprit (2nd order), but the colored glints are not from plates. They form a feature from raypath 357 in column oriented crystals. I wonder if someone has an explanation for this.
